Electrocardiogastrographic Test.—According to Menendez Feros the electrocardiogastrogram is a clinical test by which one may measure the intragastric voltage obtained by an intragastric lead in connection with an electrocardiographic apparatus. He made 500 electrocardiogastrographic tests in the presence of normal and pathologic conditions. The test offers new aid in differentiating benign or malignant gastric changes and gives some idea regarding the metabolic changes of the gastric cells. These phenomena are considered to be related to the variations of the cellular permeability or surface tension which are connected with the electrical conductibility of the gastric cells. With the technic employed by the author, the ST segment and gastric T waves have a mean value of 0.3 cm. in healthy subjects. When the intragastric voltage of these waves is between 0.1 and 0 cm., severe gastric anatomic changes might be established. In cancer of the stomach the ST segment and T waves will frequently have a high voltage. These findings are more common in the malignant cases with a short period of evolution. When benign inflammatory changes are concomitant with the neoplasm, the intragastric voltage will be between these two opposite tendencies. In gastric cancer with a low intragastric voltage due to concomitant benign inflammatory changes an injection of epinephrine will increase the voltage. In normal cases or in pure benign inflammatory changes the epinephrine does not seem to have any electrical reaction; on the contrary, it has a tendency to decrease it. The same results have been obtained in gastric allergy.

Pellegrini-Stieda Disease.—Buckley states that a history of injury to the knee joint followed by pain, swelling, tenderness in the medial aspect and restricted motion of the joint is an indication that the Pellegrini-Stieda syndrome is present. This pathologic condition should be considered in cases of sprains or contusions if the aforementioned symptoms are present beyond the usual period of recovery. Serial x-ray studies should be made in all such cases. Many months after the initial injury complaint may be made of limitation of motion and weakness and discomfort of the leg, causing a disturbed function. Secondary arthritic changes may also be present. Early cases show a swelling of the soft tissues at the inner aspect of the knee. Several weeks later a calcified mass will be noted on palpation. The calcification, if present, is firm and slightly movable but not adherent to the overlying skin. The x-ray shadow is usually directed vertically in a crescentic shape, lying adjacent to the medial femoral condyle, with a soft tissue gap between the calcification and the distal end of the femur. The lesion is best seen in the conventional anteroposterior view. The histories of the 2 patients are illustrated by roentgenograms showing the crescentic calcification in the region of the adductor tubercle.

Treatment of Malaria with Arsenicals.—Stewart treated 78 malarial survivors of a naval engagement who had tertian malaria. All had been exposed to the bite of malaria-carrying mosquitoes. They had no mosquito netting and no prophylactic medication for the fifteen days they were ashore. Immediately after being evacuated, all were given suppressive therapy consisting of 0.2 Gm. of atabrine on alternate days. The first case of malaria appeared five days later, and new ones continued to develop during the following fortnight. A routine method of treatment was adopted which consisted of bed rest and 0.65 Gm. of quinine sulfate three times daily. In a group of 10 patients who had been tried on quinine with unfavorable results, oxophenarsine hydrochloride 0.04 Gm. was given in addition to the quinine. The oxophenarsine hydrochloride was administered intravenously in a single dose to those men who had continued to have high temperatures after at least three or four days of quinine therapy. In all but 1 the temperature fell to normal within a few hours after the oxophenarsine hydrochloride injection and did not subsequently rise above 99 F. Seeing the excellent results obtained in these 10 cases, it was decided to try oxophenarsine hydrochloride on 3 unselected patients. In none of these 3 patients did fever appear subsequently, so that it became possible to put them on ambulatory treatment after only four days in the sickbay. The average hospital period of the 10 quinine resistant cases after treatment with oxophenarsine hydrochloride was three and one-half days. Reactions to oxophenarsine hydrochloride are rare. It is probably advisable to use at least four injections of 0.04 Gm. at weekly intervals following the initial treatment.

Removal of Blood from Traumatic Hemothoraces.—Extravasated blood in the pleural cavity acts as an irritant and causes an inflammatory response in the pleura. Inflammatory exudate seeps into the pleural cavity diluting the blood, and fibrous tissue commences to grow. Great fibrous thickening and even calcification of the pleura may result with prolonged or permanent respiratory disability. When the blood is efficiently removed many patients will have a dry and healed pleura within a month with no respiratory disability remaining, and those who become infected will have a small loculated empyema instead of one coextensive with the original hemothorax plus the added exudate. Treatment by repeated aspirations fits into the plan of dealing with hemothoraces in New Guinea. The needle must be of adequate bore and length. Aspiration is repeated every three days until the pleura is dry, but the interval is varied to suit each case and usually becomes longer as the effusion becomes smaller. It is a common fault to carry out aspiration at too low a level. The needle should rarely be inserted below the ninth intercostal space just medial to the angle of the scapula, the eighth just lateral to the angle of the scapula, the seventh in the posterior axillary line (usually the best to try first), the sixth in the midaxillary line, the fifth in the anterior axillary line and the fourth in the nipple line. Inexperienced men may fail because the needle enters the phrenicocostal sinus and pierces the diaphragm. It is advisable to aspirate all the fluid which can be obtained, but removing more than a pint is inadvisable because sudden and large changes in the degree of aeration or collapse in the lung should be avoided.

Methionine in Infective Hepatitis.—Higgins and his associates administered methionine to alternate patients with infective hepatitis. The total number was 37, of ages between 17 and 45 years. Care was taken to exclude patients with liver disease from other causes; no patient who had received neoarsphenamine or who had been exposed to any toxic substance was included in the experimental group. The patients were kept in bed. To minimize the chance variation of the methionine content of the meals, all patients, treated and untreated, were put on a diet of low fat and high protein content, supple-

mented with vitamins. A record was kept of the amount eaten by every patient at each meal. It was estimated that the methionine content of the diet consumed daily was of the order of 2.5 Gm. Throughout the day five 1 Gm. doses were given either in milk or after flavoring with fruit juice. Including that in the diet, the treated patients received daily nearly 7.5 Gm. of methionine. Treatment with methionine did not significantly affect the clinical course of the illness, the anorexia or the average duration of biliuria or of bilirubinemia.

Control of Infection in Wounds.—Bentley and Thomson, members of the penicillin control team in the Central Mediterranean Force, investigated the value of sulfanilamide and penicillin when applied locally in the treatment of recent wounds. In an investigation of 1,000 wounds during the battle for the Gothic Line the organism of initial sepsis was found to be Staphylococcus pyogenes aureus. The incidence of infection in wounds before operation at the casualty clearing station was about 51 per cent. In wounds undisturbed during transit and treated at the casualty clearing station by operation alone, 49 per cent were infected and 23 per cent were septic; by operation and sulfanilamide powder, 43 per cent and 11 per cent; by operation and penicillin-sulfathiazole powder, 25 per cent and 7 per cent, when examined in the base hospital five to ten days later. Thus operation alone did not completely remove infection from a recent wound. Sulfanilamide applied locally had a bacteriostatic effect; for although the infecting bacteria persisted, their activity was depressed, so that the incidence of sepsis was reduced. Penicillin-sulfathiazole powder similarly applied was more effective; its use was followed by the destruction of the infecting cocci in about one half of the infected wounds with an equally low incidence of sepsis. Wounds operated on at the casualty clearing station in under twelve hours had a lower incidence of infection than those operated on between twelve and twenty-four hours in all the chemotherapy groups. Wounds that had been redressed between casualty clearing station and base hospital had a higher incidence of infection than had those that had not been disturbed. The importance of control of infection by operation and chemotherapy at the casualty clearing station is illustrated by the results of suture. Of wounds uninfected with pyogenic organisms 80 to 85 per cent obtained grade 1 union, whether appearing clean or dirty, whereas wounds that were infected, even if appearing clean, showed a lower rate of success.

Electric Convulsions in Epilepsy.—Caplan regards epilepsy as a disturbance of the electrical equilibrium of the brain which leads to the occasional accumulation of an excessive quantity of energy. The epileptic fits can be regarded as a discharge mechanism whose function it is to disperse this energy whenever it exceeds a certain threshold value. An epileptic patient's chief disability lies in the fact that his fits are rarely predictable and may occur at any awkward moment or in situations involving considerable danger. The idea has therefore been developed of replacing these spontaneous fits by electrically induced convulsions which can be produced under controlled conditions of time and place. This therapy should not supersede the pharmacologic methods of combating the fits, but rather it should be an accessory treatment in those cases in which fits occur despite full dosage of anticonvulsant drugs. This paper is a preliminary report on 15 cases of epilepsy in which electrical convulsions were tried. In 11 cases the fits have been materially diminished. In 7 cases the symptoms of an associated psychosis have been ameliorated. The value of an induced convulsion as a means of terminating a dangerous psychic equivalent has been illustrated. No serious or alarming complications have been experienced.

*Life Span of Red Cell in Man. S. T. Callender, E. O. Powell and L. J. Witts.—p. 129.

Bacteriologic Aspects of Penicillin Therapy.—Research on the clinical application of penicillin gave Selbie and his associates the opportunity of studying this subject from the bacteriologic point of view. They found that Staphylococcus aureus is in the great majority of cases sensitive to penicillin, but variation was shown in the degree of sensitivity: 15 of 157 strains were at least eight times less sensitive than the standard strain. Streptococcus pyogenes and pneumococci were usually sensitive and showed only minor variation in susceptibility. Some of the nonhemolytic streptococci showed considerable resistance. The 10 strains of Actinomyces were less sensitive than the Oxford staphylococcus, but the majority were within the therapeutic range of penicillin. Observations on penicillin blood levels indicate that a dose of 20,000 units given intramuscularly every three hours will maintain a bacteriostatic concentration sufficient to deal with all sensitive organisms likely to be encountered. The penetration of penicillin from the blood into cavities and in particular the subarachnoid spaces (cerebrospinal fluid) is at times insufficient and has to be supplemented by direct injection. A good indication of improvement in pyogenic infections is a diminution in the blood leukocyte count. The rate of disappearance of the micro-organisms depends largely on the nature of the lesion. In acute infections they disappear as a rule in a few days but persist longer in deep foci and in areas of devitalized or necrotic tissue. This persistence is especially characteristic of lung infections, where they appear to have a purely saprophytic existence. Secondary invasion by penicillin insensitive organisms is liable to occur, especially in wounds sustained in battle or in air raids. The development of resistance to the drug was observed in a small number of instances.

Life Span of Red Cell.—Callender studied the survival of transfused erythrocytes in 3 normal male subjects of group A from whom blood was removed and replaced by blood of group O. The curve of decay of the transfused cells was linear within the experimental error; their average life was sixty days. The relation between the decay of transfused cells and the law of survival of the individual erythrocyte has been deduced. It is concluded that red cells live for one hundred and twenty days in men, which is the true average life. The normal rate of replacement is 0.83 per cent daily.

Penicillin in Clostridial Infections.—During the first weeks after D day Fisher and his associates made observations on the influence of penicillin on the incidence and course of gas gangrene and allied conditions. Penicillin should prevent the development of gas gangrene rather than treat the established condition. Inadequate "prophylactic" administration may lead to a serious clinical picture very different from that associated with either gas gangrene or anaerobic cellulitis. During the period June 8 to July 24, 3,907 battle casualties were admitted; 436 of these had been treated with injections of penicillin. These were those most liable to suffer from gas gangrene. The treatment prescribed was an initial injection of 100,000 units, followed in about six hours by 45,000 to 50,000 units at four or five hour intervals till definitive surgical treatment could be carried out. Had the selection been perfect, cases of gas gangrene and allied conditions should not have developed in those not prophylactically treated with penicillin, but such conditions developed in 28 out of a total of 3,471 cases; among these 28 were 5 cases of gas gangrene. Among the 436 prophylactically treated with penicillin 2 developed "gas" infection but none had gas gangrene. The authors discuss four groups of cases. The first group includes those first recognized as gas infection in the emergency hospital, the second group those recognized and treated before; in the two other groups gas infection was not diagnosed, but those of the third group had dirty lacerated wounds and were treated earlier with prophylactic penicillin; those of the fourth group had "clean" lacerated wounds. The diagnosis of gas infection was made on the basis of the following clinical criteria: swelling and color of muscles, thin brownish discharge, presence of gas, smell, discoloration of surrounding skin, and general condition of the patient. None of the cases of the first group had reached the stage of fulminating gas gangrene. They would be classified as "anaerobic cellulitis" or "local gas gangrene" of muscle. Bacteriologic diagnosis was made both on film and in culture. Both supported the diagnosis. The following therapeutic program was found most satisfactory: immediate injection of 20,000 units of penicillin, repeated at the beginning of operation and thereafter three hourly or by intramuscular drip, for from ten to fifteen days. Immediate injection of 50 to 100 thousand units of gas gangrene antiserum, repeated if considered necessary. Wide incision of the wound and excision of only definitely necrotic muscle. The lengthy penicillin treatment was thought necessary owing to the observation that the swelling of muscles, clostridial infection and evidences of toxemia persisted much longer than the unhealthy appearance of the muscle surfaces. As a precaution against secondary infection, penicillin paste, 250 units per gram, was applied locally as soon as systemic treatment was discontinued and till secondary suture or skin grafting could be carried out. Patients liable to develop gas gangrene should receive a penicillin injection as soon as possible after wounding, and treatment should be continued till granulations have formed on the wound surface. With a short or interrupted course of penicillin a profound or protracted toxemia may result in spite of the absence of typical local signs. In such cases the diagnosis may be missed and the patient fail to receive further penicillin or gas gangrene antiserum.

Experimental Observations on Limitations of Oil as Vehicle for Anesthetic Agents. M. Kelly.—p. 274.

Transfusion with Malaria Infected Blood.—Officer says that the use of potentially malaria infected individuals as donors for blood transfusion has been regarded as dangerous heretofore because the patient might develop malaria, but in an emergency it would be foolish to deny the benefit of transfusion to an exsanguinated patient if the malarial parasites so transmitted could be dealt with effectively by doses of quinine. Experimental transfusions of malarial blood containing large numbers of parasites have been carried out on 5 volunteer recipients. One volunteer had two such transfusions. The transfusions were immediately followed by routine antimalarial treatment. The author concludes that the development of malaria in a nonimmune recipient following blood transfusion from an infected donor can be prevented by the immediate institution of antimalarial therapy. In case of emergency a potentially malarial donor could be used for transfusion, with the knowledge that the benefit derived from the transfusion would far outweigh any ill effects resulting therefrom.

Successful Response to Penicillin in Case of Subacute Bacterial Endocarditis. B. G. Shapiro.—p. 40.
*Case of Ovalocytosis. J. Barnetson.—p. 42.
Actinomycosis Treated with Sulfonamides. C. A. H. Watts.—p. 43.

Case of Ovalocytosis.—Barnetson reports the history of a middle aged woman of European extraction who was hospitalized with symptoms suggesting chronic colitis. During a routine blood count it was discovered that 95 per cent of the erythrocytes were oval. The patient had no history of anemia, nor did the family history reveal anemia. Examination of the blood of a brother revealed that 45 per cent of the erythrocytes were oval. Ovalocytosis is an unusual and interesting abnormality of the blood. It is never associated with noteworthy anemia, and it is not related to sickle cell anemia in Negroes.

Adhesive Pericarditis.—Westermann reports results of surgical treatment in 53 cases of adhesive pericarditis. Rheumatism rather than tuberculosis plays the most important part in the genesis of the condition. The etiology is determined by the history and the postoperative course rather than by microscopic findings. The incidence of adhesive pericarditis may be reduced and the surgical treatment made more effective by combating the rheumatic infection. Of the patients 37 were male and 16 female; 15 were between the ages of 11 and 20 years, 19 patients between 21 and 30 years. The second and third decades of life show the highest incidence. Conservative treatment proved ineffective. Pericardiectomy was performed in all of the cases except 1, in which Brauer's operation was first performed. A two stage pericardiectomy by combining the transthoracic and the anterior fenestration method was performed in 2 cases. A large anterior window-like opening with a lateral pedunculated flap after Kocher was used in the one stage pericardiectomy in all the other cases. Complete recovery took place in 19 cases and considerable improvement in 15. The mortality rate was 35.8 per cent. Recovery and improvement in two thirds of the cases is to be considered as a highly satisfactory result in spite of the still high mortality rate. New adhesions from regenerating ribs and the systolic drawing in of the thorax may be prevented by the complete removal of the posterior periosteum of the ribs and by covering the heart with a soft cutaneous muscle flap. Precardiac cardiolysis may be combined with radical excision of the pericardium. This specific combination is to be considered as the essential factor on which the permanent results depend. Cooperation of the surgeon with the internist is important, since even better results may be obtained from pericardiectomy when performed in an early stage of the disease.

Wartime Toxic Diffuse Goiter.—Wartime toxic diffuse goiter does not represent a specific form of toxic diffuse goiter as to origin, clinical aspect, treatment or prognosis. A single physical exertion or a single instance of mental excitement, as well as prolonged mental or physical strain continuing for weeks or months, may be the eliciting factor in soldiers and in civilians alike. Toxic diffuse goiter must have been latent in these persons, since a specific change in the thyroid depending on an individual predisposition is to be considered as the principal cause of the disease. The incidence of fully developed toxic diffuse goiter was low during the first world war and has proved the same during the present conflict. The incidence of mild forms has been high, and differential diagnosis from purely nervous heart disorders and disturbances of circulation may be difficult. As observed by Gattig, in 4 of 5 soldiers the toxic diffuse goiter presented a gradual development of medium severity within one year. In the fifth soldier the sudden onset of the disease could be traced to the fact that he was buried under the falling fragments of a shelter which had been hit by an artillery shell. In 3 civilian patients the night bombardment of their homes was the eliciting cause of the disease, which developed within a few days after the bombardment. A mortal fear reaction however was missing at least in 1 instance in which the patient immediately regained his self control by helping to save other persons from the wreckage. Treatment of wartime toxic diffuse goiter does not differ from the usual treatment, but the results of Plummer's treatment, as well as the recovery rate, are less satisfactory in secondary toxic diffuse goiter in wartime than in primary toxic diffuse goiter.

Acta Medica Scandinavica, Stockholm

Sedimentation Rate and Room Temperature. T. Romanus.—p. 535.

Intrasternal Administration of Heparin.—Lindgren and Walldén administered 57 mg. of heparin regularly at six hour intervals by intrasternal injection and found that the effect on the coagulation time was the same as when it was given intravenously. In view of the need of repeated injections, the needle can remain in the sternum; this is much easier than to keep a needle fixed in the cubital vein. The intrasternal method is recommended as an improvement in technic.

Paroxysmal Paralytic Hemoglobinuria.—Louw and Nielsen differentiate between exogenous and endogenous forms of hemoglobinuria. With the endogenous forms they group cold hemoglobinuria, march hemoglobinuria, chronic hemolytic anemia (Marchiafava type) and paralytic hemoglobinuria or myoglobinuria. This last form is rare, only 4 cases having been reported previously. After reviewing these cases, the authors describe myoglobinuria in a boy aged 10 who had a history of repeated attacks of muscular pain and difficulty in walking since the age of 4 years. During an acute attack, when the boy was admitted to the hospital, the urine was dark reddish brown and gave a strong reaction for blood. Spectroscopic analysis showed that myoglobin was excreted in the urine during the attack, at which time there was also creatinuria. The boy was feeling well at his discharge. The appearance of 8 cases of progressive muscular dystrophy in the family of this boy suggested that progressive muscular dystrophy and paralytic myoglobinuria may be different forms of the same disease, the latter representing the acute manifestation of the lesion, while progressive muscular dystrophy is the chronic form.

Thrombophlebitis Saltans.—In Feltström's case of venographically verified thrombosis in the right leg and thigh the course was normal for a few days after heparin treatment, but new disturbances atypical both for thrombosis and for the usual banal thrombophlebitis affected in turn different segments of the walls in the deep veins in the right and left leg, with secondary thrombus formation. Heparin treatment at once stopped the fresh thrombotic process but seemed powerless against further spread of the pathologic process. Recovery resulted after treatment with injections of estrogen.

Etiology of Prostatic Hypertrophy.—Törnblom says that it is uncertain whether hypertrophy of the prostate is due to endocrine disturbances. Endocrine treatment therefore is a shot in the dark. The favorable effects attributed to treatment with testosterone propionate may depend on a generally stimulating action of this preparation

Book Notices

Handbook of Physical Medicine. Selections Authorized for Publication by the Council on Physical Medicine, American Medical Association. Previous editions of this work were published under the title of Handbook of Physical Therapy. First edition. Cloth. Price, $2. Pp. 392, with illustrations. Chicago: American Medical Association, 1945.

The first edition of the Handbook of Physical Medicine is actually the fourth edition of the Handbook of Physical Therapy. It was prepared under the auspices of the Council on Physical Medicine of the American Medical Association. Physical medicine includes the diagnosis and treatment of disease by various nonmedical means. It employs the physical and other effective properties of light, heat, cold, water, electricity, massage, manipulation, exercise and mechanical devices for physical and occupational therapy in the diagnosis and treatment of disease.

The Handbook of Physical Medicine represents a summary of the efforts of the Council during a twenty year period to separate the beneficial from the useless in this form of therapy, to evaluate the various physical therapeutic agents and the methods of their employment and to protect the medical profession from the snares and pitfalls found in this field.

When Dr. Joseph F. Smith brought a resolution before the House of Delegates of the American Medical Association urging the Board of Trustees to establish a Council on Physical Therapy, the board chose nine men from the ranks of chemists, physicists, pathologists, physiologists, radiologists and clinicians to compose the Council. Later the membership was increased to twelve. In 1944 the Board of Trustees changed the name to the Council on Physical Medicine.

Many members of the medical profession, representing the various specialties, have acted as referees or consultants for the Council. These men have tested physical agents and apparatus submitted for acceptance, studying the therapeutic claims made for them, evaluating the merit of special articles submitted for publication and aiding in the educational work of the Council.

The Council's aims and purposes are threefold: 1. To protect the medical profession and thereby the public against inefficient and possibly dangerous apparatus and against misleading and deceptive advertising in connection with the manufacture and sale of devices for physical therapy. 2. To disseminate such reliable information as it possesses or may acquire and to stimulate instruction to aid the practicing physician in choosing true and sound physical therapeutic methods. 3. To act in an advisory capacity to the profession and to the public in all matters concerning this branch of medicine. The work of the Council has progressed along two distinct lines: 1. The evaluation of the efficacy of physical therapeutic apparatus, usually but not always submitted for Council consideration, through a study of the therapeutic claims made for such devices; the elimination of false, misleading or exaggerated statements in advertising matter concerning the equipment and the publication of the Council's acceptance or rejection of the given physical agent in THE JOURNAL. The booklet Apparatus Accepted can be obtained free of charge by writing to the Secretary of the Council. 2. The improvement of the type of physical therapy practiced by the profession.

Some of the subjects discussed are evaluation of methods used in physical therapy; physiologic effects of heat; heat in surgical and orthopedic conditions; fever therapy; physiology of massage; body mechanics and posture; therapeutic and remedial exercise; occupational therapy; hydrotherapy; colonic irrigation; electrical stimulation of muscle; medical diathermy; electrolysis; ultraviolet and infra-red radiation used in therapy; physical therapy in the treatment of fractures, in infantile paralysis, in psychiatric practice and in skin diseases.

Neuro-Ophthalmology. By Donald J. Lyle, B.S., M.D., F.A.C.S. Fabrikold. Price, $10.50. Pp. 395, with 234 illustrations and 7 charts for recording lesions affecting the visual system. Springfield, Ill.: Charles C Thomas, 1945.

This work deals with the relationship of the eye to the brain, showing the effect of certain diseases of the brain on the eyes. An attempt is made to obviate the necessity of referring to the many textbooks on neurology so as to glean from here and there, with much time consuming effort, information pertaining to neuro-ophthalmology. The plan is to bring together in brief but comprehensive and coordinated manner those many phases of neurology as far as they concern, directly or indirectly, neuro-ophthalmology. The first twelve chapters are devoted to embryology, anatomy, pathology, physiology and morphology. The remaining seven chapters include a thorough discussion of the various infections, diseases and tumors that affect the brain and eye. The chapter on intracranial and orbital neoplasms is especially comprehensive, although no attempt is made to include a classification of brain tumors.

There are 130 necropsy or operatively confirmed case histories, which have been outlined in connection with the text. There are many retinal photographs of ocular conditions, about half of which are stereoscopic and so placed that one can observe them through the stereoscope in order to obtain depth perception. Several charts for recording lesions affecting the visual system are included. The final chapter includes a discussion on eye manifestations of head injuries, which should be of vital interest to every ophthalmologist. This book should be welcomed by many ophthalmologists, neurologists and neurosurgeons because this vast subject matter is correlated into a working unit.

A Textbook of Pathology: Pathologic Anatomy in Its Relation to the Causes, Pathogenesis, and Clinical Manifestations of Disease. By Robert Allan Moore, Edward Mallinckrodt Professor of Pathology, Washington University School of Medicine, Saint Louis. Cloth. Price, $10. Pp. 1,338, with 513 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

In writing a textbook of pathology, an author must ask himself "Is this a book for students?" or "Is it for practicing physicians?" or "for specialists in pathology?" The approach to these various avenues would imply stressing fundamental problems of interest to different groups. However, in recent years writers in the various branches of the medical subjects have sought to include and correlate the fundamental sciences as part of their discussion for a better understanding of disease problems. Anatomy, physiology, chemistry, bacteriology and pathology are the pillars supporting the framework about which the better understanding of the cause and effect, the pathogenesis and epidemiology of disease and the effectiveness of the therapy is better understood. Physicians today do not have to "guess" what the nature of the patients' ailments are, they need only evaluate the objective and subjective findings in terms of the basic sciences. Therapy should not be empirical but placed on a scientific level of understanding the reasons for the drug which is prescribed for the patient.

Moore has achieved some of these objectives. As he has indicated, his textbook on pathologic anatomy is presented in its relation to the causes, pathogenesis and clinical manifestations of disease. This is an excellent approach, for, as Moore has demonstrated in his book, pathology can and should be made dynamic. Gone is the era of the pure morphologist, the dead house pathologist; and this important subject of pathologic anatomy must be presented in an interesting, understanding and vital manner. The clinical pathology conferences, the surgical, neurologic and various other branches of medicine in which the clinician and pathologist meet to discuss their medical problems throughout hospitals and teaching institutions in this country are indicative of the cooperative manner in which physicians work for the benefit of their patients and the community. But to interest the clinical branches in medicine along this line of thinking it was necessary for the pathologist to make his branch of medicine a vital and integral part of the whole. The clinician thinks in terms of pathology, the pathologist analyzes and interprets his subject in terms of clinical medicine.

Moore has presented his material in an interesting manner. As a teacher in pathology he understands the needs of the student. This is manifest in his book by his arrangement of the subject matter according to the causative agent or agents. In a simple, concise and lucid manner the subject is discussed. Long, uninteresting discussions are eliminated for the sake of brevity. There is too much material presented for detailed review; the literature (mostly in English) at the end of the chapter can be further studied by the interested reader. If a disease is designated by the discoverer's name, Moore tells the reader who this person is or was. Virchow, Rokitansky, Koch,

Cohnheim, Bright, Councilman, Welch, Wells are not mere names; they mean something to the student who reads about the disease which these men have described. A discussion on physiologic alterations, chemical changes, bacteriologic factors is interwoven in the discussion, so that the student now has an understanding of the alterations in form and disturbances of function that take place in disease to prepare him for his better understanding of clinical medicine.

Moore also discusses deficiency diseases, tropical medicine, diseases of unknown or obscure cause and the virus diseases. Thus the practicing physician and specialist in pathology may find in this book information which will benefit him in his specialty.

We do not wish to imply that this textbook is the answer to all the problems in pathology for the clinician and the pathologist. There are several examples that one can cite that the reader may take exception to. To cite just one example, the histogenesis of tuberculosis is not complete; the formation of caseation necrosis and the mechanism of bone formation could be discussed in more detail. But these are minor compared to the overall subject matter presented. Practically every phase of pathology has been discussed, and in a textbook of pathology of this size some detailed phases must be eliminated for the sake of the overall subject matter.

The text is clear and the illustrations have been well selected. There is a good index. The book can be highly recommended and should be in the library of students, physicians and hospitals.

Tropical Nursing: A Handbook for Nurses and Others Going Abroad. By A. L. Gregg, M.A., M.D., M.Ch., Member of Associate Staff of Hospital for Tropical Diseases, London. Second edition. Cloth. Price, $3. Pp. 185, with 13 illustrations. New York: Philosophical Library, 1944.

Some of the most important information in this handbook is included in the introduction and the chapter on personal hygiene in the tropics. The advice offered to one going to the tropics for the first time is sound and might well be heeded. The diseases are treated briefly and in an elementary fashion. The descriptions are hardly complete enough for the nurse to risk a differential diagnosis and start treatment in the absence of a doctor. The nursing procedures referred to are all ones employed in illnesses of temperate climates and in effect deny the existence of a field of "tropical nursing." However, the important part that insect vectors play in transmission of tropical diseases is aptly stressed with its relation to the nursing problems. A section on technic which outlines blood examination, blood transfusion, bowel lavage, the test meal, intramuscular injection and intravenous injection is a simple review for handy reference. The section on care of the eyes in the tropics includes injury from intense sunlight and that due to insects. The glossary of tropical terms contains few terms restricted to tropical medicine. A table of weights and measures is included for reference purposes.

Textbook of Anaesthetics. By R. J. Minnitt, M.D., D.A., Director of Anaesthetics, David Lewis Northern Hospital, Liverpool, and John Gillies, M.C., M.B., Ch.B., Consultant in Anaesthetics, Department of Health for Scotland. With a chapter on Local and Regional Analgesia by L. B. Wevill, M.B., F.R.C.S., Major R. A. M. C., which includes a section on Its Application to Dentistry by Dr. John Boyes, Dental Surgeon in charge, Facio-Maxillary Unit, Bangour E. M. S. Hospital, Scotland. Sixth edition. Cloth. Price, $7. Pp. 487, with 199 illustrations. Baltimore: William Wood & Company, 1944.

The former "Handbook of Anaesthetics" by Ross and Fairlie was revised in a fifth edition in 1940 by R. J. Minnitt. This, the sixth edition, has been rearranged and largely rewritten by R. J. Minnitt of Liverpool and John Gillies of Edinburgh. The scope of the book has been considerably extended to conform to the change in name to "Textbook of Anaesthetics." In general, the authors are to be congratulated on the changes and additions. It is now a book which probably is honestly and fairly representative of the thought and practice among a majority of British anesthetists. Certain points of disagreement with the opinions held in this country are present and to be expected. That the effort deserves to be called a textbook of anesthetics would be questioned by many. As a pleasant and profitable means of familiarizing oneself with modern British practice in anesthesiology, it should prove useful to the medical profession in this country.

The Foetal Circulation and Cardiovascular System, and the Changes That They Undergo at Birth. By Alfred E. Barclay, O.B.E., D.M., F.R.C.P., Kenneth J. Franklin, D.M., F.R.C.P., and Marjorie M. L. Prichard, M.A. Cloth. Price, 50s. Pp. 275, with 160 illustrations. Oxford: Blackwell Scientific Publications, Ltd., 1944.

Seven years ago Dr. A. E. Barclay, the dean of British roentgenologists, decided to tackle the problem of determining exactly what happens in the circulation when a placental animal is born; he wanted particularly to determine the time of functional closure of the ductus venosus. In order to facilitate this research, Dr. Barclay devised a cineradiographic apparatus and joined forces with Dr. Kenneth J. Franklin and Marjorie M. L. Prichard.

The book which describes their studies begins with a fine chapter on the history of the problem and what has been learned —mainly by the anatomists and embryologists. The next chapter is on the course of the blood flow in the fetal animal—mainly the lamb—as determined with the help of cineradiography and an opaque medium in the blood vessels. Chapter III reports a detailed study of the behavior of the many parts of the cardiovascular system in the mature fetal lamb. Chapter IV is on the circulation of the mature fetal lamb and the respiratory mechanisms which take over after birth. Chapter V is on lambing as it is observed by shepherds. Chapter VI is on the changes which occur during and shortly after the birth of the lamb. These changes are listed in approximate order on pages 126 and 127. The exact order has not yet been established for all the changes, but the authors have evidence for the view that there is a functional closure in the ductus venosus, then in the via sinistra and then in the ductus arteriosus. Functional closure precedes anatomic closure. There is a discussion of the factors which bring about respiration and the big changes in the circulation. Chapters VII and VIII are on comparative physiology, and chapters IX to XII are on the changes at birth in the human fetus and infant.

As Galen so truly said a thousand years ago, while describing the via sinistra and ductus arteriosus, the closure of these fetal channels at the birth of an animal is an even more wonderful phenomenon than was their original creation.

The book is beautifully illustrated and there is a fine bibliography. It doubtless will long stand as a classic in the literature on the physiology of the circulation. It should serve also as a beautiful example of what a man can accomplish in spare time when he is past 60 and working hard for his government—during years when his country is fighting a desperate battle for its life.

Myasthenia gravis. Por el Dr. Adalberto R. Goñi, jefe de clínica médica del Servicio sanitario de correos y telecomunicaciones. Paper. Pp. 135, with 10 illustrations. Buenos Aires: Librería y editorial "El Ateneo," 1944.

Mysthenia gravis is such a rare disease that there has been no monograph written on the subject for nearly forty years. Since 1934, when Walker discovered the striking effects of neostigmine (prostigmine) on the symptoms of myasthenia gravis, many cases have been reported and papers on research are now appearing at the rate of about twenty-five a year. Goni reports in detail 13 cases observed since 1937 in Buenos Aires and its vicinity and reviews in an adequate manner the history of our knowledge of this disease and its clinical as well as pathologic aspects. His chapter on the pathologic physiology of myasthenia gravis is published in collaboration with Alfredo Lanari, a physician who has done considerable investigative work both in this country and in Buenos Aires. This monograph is up to date, with an extensive list of references to the current literature and an adequate index. There are a few illustrations. The book, an extremly creditable volume, is, without question, the best treatise on the disease in print at the present time.

Diseases of the Nervous System in Infancy, Childhood and Adolescence. By Frank R. Ford, M.D., Associate Professor of Neurology, The Johns Hopkins University, Baltimore. Second edition. Cloth. Price, $12.50. Pp. 1,143, with illustrations. Springfield, Ill.: Charles C Thomas, 1944.

This excellent work continues to maintain its high standard. The author has eliminated the minor errors that creep into every text and has added new material. The index has been amplified extensively. This improved edition can be highly recommended for pediatricians and neurologists.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MIXED INSULINS

To the Editor:—What is the consensus as to the efficacy of the mixed insulins, i. e. regular and protamine insulin and of globin insulin? Are any mixed insulins on the market as yet? Captain, M. C., A. U. S.

[This question was referred to two qualified consultants, whose respective replies follow.—ED.]

ANSWER.—The combination of standard insulin with some type of delayed action insulin (protamine or globin) has been employed by all physicians experienced in the handling of severe diabetes for some years. It has been recognized that delayed action insulin, though it approached nearer the desideratum of supplying insulin for utilization at the physiologic rate than did multiple injections of standard insulin, still left something to be desired. The experience of many workers is reported in the literature of the past few years, with the consensus being that a combination of the two types of insulin works out best in those severe cases that do not regulate well on either of the insulins when used uncombined. The article by Colwell reviews the literature and sums up the present status admirably.

Globin insulin has now been given a thorough clinical trial. At first it was hoped that, because it was administered as an unprecipitated type of delayed action insulin, presumably precipitating in the tissues after injection, it would prove to be the ideal type, having a quick acting and delayed acting quotient. From clinical experience, however, it has seemed to act much like its precursor, protamine insulin.

Some of the pharmaceutical houses have been working on a mixed type of insulin, one that contains a quick action and a delayed action element. At the present time there are no mixed insulins on the market.

ANSWER.—Various attempts have been made to devise an insulin preparation having prolonged activity but also exerting a rapid effect. The ultimate aim is the maintenance of good control in the great majority of diabetic patients with a single injection daily. Protamine zinc insulin alone will control about half of all diabetic patients, the milder cases requiring 40 units or less per day. More severe cases require more rapid insulin action than is afforded by the slowly absorbed protamine zinc insulin. Good regulation may be established in many of these more severe cases by giving separate morning injections of protamine zinc insulin and of regular insulin such as protamine zinc insulin 45, regular insulin 15 or protamine zinc insulin 60, regular insulin 20, and so on. In such treatment the dose of protamine zinc insulin is usually about three times the dose of regular insulin. The results are usually satisfactory, but two injections are required, even though both are administered before breakfast.

If regular and protamine zinc insulins are mixed in the syringe or in a vial, the resultant preparation will give an intermediate type of effect (provided the regular insulin: protamine zinc insulin ratio is 1:1 or greater, since a large part of the regular insulin is precipitated by such admixture). Good clinical control may often be established by using mixtures containing 2, 2½ or 3 parts of regular or crystalline insulin to 1 part of protamine zinc insulin.

Globin zinc insulin has not yet, according to the comparative studies available, proved to offer any considerable advantages as an intermediate type of insulin. It frequently permits after breakfast hyperglycemia of excessive degree and often causes midafternoon hypoglycemia. It is completely absorbed in less than twenty-four hours, so that the advantageous overlapping effect of protamine zinc insulin is lost.

MacBryde and his co-workers have obtained results superior to those secured with extemporaneous insulin mixtures by using a single injection daily of modified protamine zinc insulin containing half or less than half as much protamine as market protamine zinc insulin (0.5 or 0.625 mg. per hundred units instead of 1.25 mg.). This market protamine zinc insulin has two components: (1) 75 per cent of any given dose is in precipitated form and is slowly absorbed throughout a period of twenty-four hours or longer; (2) 25 per cent is in solution and is rapidly absorbed, acting to control the blood sugar rise after food intake. This proportion of slow to rapid activity was selected after an analysis of 350 cases showed that it fitted the requirements of the great majority of diabetic patients. The St. Louis investigators feel that the use of variable extemporaneous mixtures has perhaps been a necessary step in developing information as to the most desirable time-activity pattern of an intermediate insulin. They believe that the use of mixtures should be discouraged because the results are irregular and the problems of mixing are confusing to patients and physicians. Since 90 per cent of a series of 110 patients were well regulated with modified protamine zinc insulin, there seems to be no necessity for the prescription of individual insulin mixtures. Other investigators have confirmed the good results obtained with market protamine zinc insulin by the Washington University group.

It seems likely that some form of modified protamine zinc insulin containing much less protamine than is present in market protamine zinc insulin will eventually completely displace the latter. There is as yet no modified protamine zinc insulin on the market. Until such a preparation becomes available it is probably best to give two separate injections, one of protamine zinc insulin and the other of regular insulin, before breakfast daily to patients not well regulated with protamine zinc insulin alone.

RATE OF TRAVEL OF CLOT IN BLOOD STREAM

To the Editor:—What is the rate of travel of an embolus in the blood stream of the veins as to the time it takes to go through the right auricle and ventricle and reach the lung?

A. P. George, M.D., Haverhill, Mass.

ANSWER.—It is assumed that the inquiry relates to the passage of a blood clot and not to that of air or fat from the peripheral veins to the pulmonary artery. Naegeli and Janker in their studies on experimental embolism with the help of a moving picture film saw that an opaque embolus, injected into the femoral vein, passes up the abdominal vena cava, hesitates for a while at the diaphragm and then shoots along the thoracic vena cava to the right auricle; even from here the embolus may come back again to the diaphragm before negotiating the transit through the heart. Certainly there is evidence of retrograde flow in the vena cava of the experimental animal. The liver enlarges in right heart failure, and in cinematographic studies of animals it has been shown that such failure is associated with regurgitation of blood from the right side of the heart into the liver. A similar temporary backflow can occur at each expiration when the liver is compressed during inspiration.

In man the rate of travel of the embolus would depend on the actual circulation time as determined by ether or decholin, on the rate and depth of respiration and on the rise in pressure in the right heart and pulmonary artery. Judging from observations in man, a sudden attack of dyspnea, cyanosis or retrosternal pain follows a sharp, tearing feeling in one of the extremities within fractions of a minute. This rate of travel is not to be confused with a slowly ascending thrombosis, which may take several days from the plantar veins of the foot to the iliofemoral segment but may break loose at any time during its progress.

DRUGS HAVING CURARE-LIKE ACTION ON MOTOR NERVES

To the Editor:—What drugs may be employed to produce motor paresis of isolated muscles, the drug being injected into the muscle?

Lieutenant Commander, MC(S), U.S.N.R.

ANSWER.—Drugs having a curare-like action are magnesium, which acts on the peripheral muscles, and quinine, which in addition increases the refractory period and slightly inhibits cholinesterase. Curare itself interrupts the nervous impulse at the neuromuscular junction. Synthetic curare-like compounds such as quinine methochloride, quinine ethochloride and salts of erythroidine act in a similar manner. Onium salts in general possess a curariform action. Atropine antagonizes or prevents the action of acetylcholine, acting directly on the effector cell, plain muscle and gland cells and renders them insensitive. The local injection of 0.1 to 0.2 per cent solution of procaine or some other local anesthetic blocks the centripetal proprioceptive impulses and thereby relaxes muscular tonus, normal

and abnormal. Neuromuscular transmission is weakened so that the muscle responds better to direct than to nerve stimulation. Cold, fatigue, low potassium, excessive calcium and strong current (cathodal depression) are well known conditions unfavorable to conduction.

RESTORATION OF BODY FIGURE AFTER PREGNANCY

To the Editor:—A prospective mother aged 22 is interested in regaining her figure after parturition. The main problem is her breasts, which before pregnancy were large but well formed and not pendulous. They have enlarged considerably by now, the seventh month of pregnancy. What measures taken both before and after delivery will insure a return of the breasts to as nearly as possible their original state? Will the wearing of a brassière while sleeping help? Does nursing the baby tend to make the breasts pendulous? What forms of exercise, if any, are of benefit to breast uplift? Are any exercises advisable ante partum? What measures do actresses generally take to preserve their figures?

Lieutenant (jg), (MC), U.S.N.R.

ANSWER.—There is little authentic information concerning the proper care of the breasts during pregnancy in order to retain their firm, normal appearance. The enlargement of the breasts is due partly to the development of the secretory acini and partly to the growth of the duct system. Proper support without compression throughout the pregnancy will prevent the excessive stretching of the tissues as a result of the increased weight and size of the breasts; it will also prevent an excessive pull on the pectoral muscles. Gentle but superficial massage of the skin with a bland cold cream may reduce the tendency toward striae.

Nursing does promote changes in the breasts, and they tend to become pendulous and flabby, rarely returning to their previous state. A properly fitting support should be worn for several months after delivery. The usual puerperal exercises are recommended, although they will not alter the tone of the breasts.

There are no special measures that actresses take to preserve their figures. The following suggestions will help: The weight gain during pregnancy should be restricted to no more than 16 to 18 pounds (7-8 Kg.). A balanced high protein diet will assure good nutrition. Daily exercises outdoors, particularly walking, will maintain good muscle tone. A properly fitting abdominal support after the fifth month of gestation will provide support for the pelvic girdle. Care at the time of delivery to prevent much separation of the abdominal muscles will assure a return of the normal appearance of the abdomen. Regulated exercises for at least eight weeks following delivery will go far to restore the figure to the normal.

DOSAGE OF TESTOSTERONE PROPIONATE

To the Editor:—I have been administering 25 mg. of testosterone propionate intragluteally three times weekly to a vigorous man in his middle seventies who complained of inadequate energy, impaired memory for recent events and general letdown. The patient believes that he has experienced some improvement from this treatment and is insistent on larger dosage. I am hesitant to administer a greater dosage, but my hesitancy is not based on any knowledge of possible harmful effects. Is prolonged administration of testosterone in amounts of 25 mg. or more three times weekly inadvisable?

M.D., Indiana.

ANSWER.—Symptoms such as those mentioned could be expected in a man of this age to be the result of the aging processes. It is also quite possible that these symptoms could be initiated to some extent by a definite decrease or loss of sex function. If the patient does not have pronounced hypertrophy of the prostate and if there is no evidence of a possible cancer of the prostate, one might be justified in increasing the dosage of testosterone propionate to 50 mg. three times weekly without fear of harm to the patient. However, it should not be administered to a man of this age for the purpose of increasing potency, which might result from doses of 50 mg.

The 25 mg. dose is usually adequate when the preparation is given for its tonic effect; this dosage is also effective in relieving the symptoms of the climacteric in younger men, in patients having hypogonadism or undeveloped testes and in castrates.

MAPHARSEN AND BISMUTH IN CEREBROSPINAL SYPHILIS—INJECTION TECHNIC

To the Editor:—I have been using iodobismitol or sobisminol with mapharsen in cerebrospinal syphilis, including tabes dorsalis and taboparesis, attaining serologic reversal. If serologic reversal can be attained in this way is there additional advantage to be gained by using tryparsamide or malaria fever therapy? I can persuade my patients to bear the pain of the injection, but the induration of the buttock becomes extremely severe—to the point where further injections are almost impossible. Do tryparsamide and malaria fever therapy have any advantages over bismuth subsalicylate in cerebrospinal syphilis? I have not read anything on the subject since the original work of Hanzlik.

M.D., Ohio.

ANSWER.—It has been the experience of the majority of syphilologists that mapharsen and bismuth do not reverse the reaction of the spinal fluid to negative in patients with tabes dorsalis or taboparesis. The blood serologic tests may become negative in tabes dorsalis without treatment of any sort, but rarely do mapharsen and bismuth cause a significant change in the blood or spinal fluid reaction of a patient with taboparesis. In other words, the experience of the inquirer is quite contrary to that reported in most of the literature during the past twenty years. In fact, mapharsen, as a rule, is less efficient in the treatment of cerebrospinal syphilis than is neoarsphenamine or arsphenamine, and the use of tryparsamide and fever therapy has become popular because their use for the patient with cerebrospinal syphilis has demonstrated their definite superiority over any of the preparations of arsenic or bismuth. Iodobismitol and sobisminol do not have any therapeutic advantage over bismuth subsalicylate.

It is probable that the local reactions to bismuth as mentioned are due to improper technic of injection. Consideration of the following factors may overcome some of the difficulty in technic: 1. The injection may be too superficial; a needle 2½ inches long should be employed. 2. Deposit of bismuth in the injection tract may occur at the time of withdrawing the needle. 3. Massage of the buttock should follow withdrawal of the needle. 4. The injection should be made with the patient lying on the table completely relaxed and not while the patient is standing or leaning over a table or chair. 5. Exercise and a sitz bath after the injection may be helpful.

INJECTION THERAPY FOR PAIN IN THROMBOPHLEBITIS

To the Editor:—I understand that injection of the lumbar sympathetic nerves is indicated for the relief of vasospasm caused by thrombophlebitis. What is the technic? What textbook or journal is recommended for additional information on the procedure?

Clauss B. Strauch, M.D., Hazel Green, Wis.

ANSWER.—Thrombophlebitis, by irritating directly or reflexly the sympathetic fibers which course along the blood vessels of the extremities, does produce vasospasm. This is manifested by a cool cyanotic extremity, with pulses diminished as compared with those on the other side; there is also a diffuse severe cramping sensation, a pain of vasoconstriction, which defies any known pattern of peripheral pathways. Under such conditions paravertebral infiltration of the regional sympathetic nerves relieves pain, decreases edema and increases peripheral blood flow. It must be emphasized, however, that not all cases of venous thrombosis exhibit these phenomena; those in the lower part of the leg are notoriously bland and are apt to give rise to embolism without much collateral vasospasm.

CARRIERS OF HEMOLYTIC STREPTOCOCCUS

To the Editor:—A boy aged 4 years has hypertrophied tonsils and chronic cervical adenitis. Culture of material from his throat reveals hemolytic streptococci. Should there be any restrictions against his contacts with other children, such as those incidental to attending nursery school, playing with preschool children or eating in a dining room where other young children are present?

Daniel Haffron, M.D., Elgin, Ill.

ANSWER.—Group A hemolytic streptococci are pathogenic for man. A child carrying this organism in the throat is capable of spreading infection to other children, and restrictions are usually considered to be advisable although not specifically required under the department of health regulations for the state of Illinois.

THE ANOXIA TEST IN THE DIAGNOSIS OF CORONARY INSUFFICIENCY

A STUDY OF 289 CASES

RAYMOND D. PRUITT, M.D.
Member of Division of Medicine, Mayo Clinic
ROCHESTER, MINN.

CAPTAIN HOWARD B. BURCHELL

AND
ARLIE R. BARNES, M.D.
ROCHESTER, MINN.

The diagnosis of coronary sclerosis is usually dependent on the clinical history of pain in the chest or arm, invoked by effort and relieved by rest. In certain cases an apparent constant correlation exists between the occurrence of pain and the amount of increased demand on the heart for work, but in many other cases the occurrence of pain is not related consistently to increased effort or other cause. Because of the vagaries of the symptom complex of angina pectoris, the diagnosis may be difficult to establish. Consequently, any objective method for confirming or excluding a diagnosis of coronary sclerosis would be of immediate interest to the clinician, particularly if the test was applicable from the standpoint of time and material, was harmless to the patient and could be definitely interpreted.

A number of observers have noted the reaction of so-called normal persons and of persons who have coronary disease to low percentages of oxygen, particularly in regard to electrocardiographic changes. The medical profession is indebted, however, to Levy and his associates [1] for their efforts to introduce a standardized test which might aid in the diagnosis of coronary sclerosis in difficult cases. Their continued studies, together with the work of Barach and others [2] and of Greene and Gilbert [3] have clarified many of the puzzling observations that originally were made in use of this procedure.

In studies of the electrocardiographic effects of anoxia, Levy and his associates used a mixture containing oxygen 10 per cent and nitrogen 90 per cent. On the basis of their experience they defined certain criteria for the electrocardiographic changes associated with, and indicative of, coronary insufficiency. These they summarized as follows: [4] 1. The arithmetic sum of the RS-T deviations in all four leads (1, 2, 3 and 4F) is 3 mm. or more (fig. 1). 2. Partial or complete reversal of the direction of the T wave in lead 1 is accompanied by an RS-T deviation of 1 mm. or more. 3. Complete reversal of the direction of the T wave in lead 4F is present regardless of any associated RS-T deviation in this lead (figs. 2 and 3).

Moreover, they stated that "strong presumptive evidence of diminution in the coronary reserve is afforded by the occurrence of pain during a test which is electrocardiographically negative. The successful use of pain as an index will depend upon the observer's ability to differentiate it from the minor discomfort of an apprehensive subject, and his astuteness in detecting the occasional malingerer."

MATERIAL

At the Mayo Clinic during the last two and a half years the anoxia test has been performed in 300 cases. The present analysis is based on the results of the test in 289 of these cases. Evaluation of the patient's history and physical findings preceding the test disclosed symptoms or physical findings suggestive of coronary insufficiency in all but 7 cases. The clinical diagnosis was not established conclusively in any case prior to performance of the anoxia test.

The oldest patient was 67 years of age and the youngest was 24. Six patients were in the third decade of life, 57 in the fourth, 112 in the fifth, 94 in the sixth and 20 in the seventh.

The test never was performed in the presence of congestive heart failure or within four months after a suspected cardiac infarction or more than once in twenty-four hours in the same case.

METHOD

The method devised by Levy was used with only minor modifications. By means of a reservoir bag and a mask the patient breathed 10 per cent oxygen and 90 per cent nitrogen from a cylinder containing this mixture. A tank containing 100 per cent oxygen was included in the apparatus, and a flood valve permitted almost instantaneous replacement of the 10 per cent oxygen mixture by 100 per cent oxygen.

The test was performed under basal conditions. The usual period of observation was twenty minutes. Electrocardiograms were made before the test and ten and twenty minutes after the patient began to breathe the mixture containing 10 per cent oxygen. If the patient experienced pain during the test, an effort was made to secure final tracings before changing from 10 to 100 per cent oxygen; however, if the distress seemed severe, 100 per cent oxygen was given at once. On completion of the test, 100 per cent oxygen was given routinely for from one to two minutes, a time adequate for the subsidence of cyanosis.

The electrocardiograms included the three standard leads and the precordial leads designated 4R and 4F (terminology of American Heart Association).[5]

RESULTS

On the basis of clinical evidence alone, the 289 persons subjected to the anoxia test were divided into four groups, as follows: group 1, controls; group 2, patients who had an essentially positive history for coronary insufficiency; group 3, patients who had an equivocal history, and group 4, patients who had an essentially negative history. In the following summary the expression "electrocardiographically positive test" indicates that during the anoxia test there were electrocardiographic changes of a type and degree satisfying one of the criteria of Levy.

Group 1 was composed of 7 healthy men who had experienced no symptoms suggestive of angina pectoris. None of these men experienced pain during the anoxia test and no significant electrocardiographic changes occurred.

Group 2 was composed of 92 cases in which a history highly suggestive of angina pectoris was obtained. This diagnosis probably would have been made, perhaps with some slight reservation, even if the anoxia test had not been performed. When the result of the test was positive, it was regarded as confirmatory evidence of coronary insufficiency. When the result of the test was negative, the tentative diagnosis based on clinical grounds, nevertheless, was maintained.

Of the 92 patients, 53.2 per cent had electrocardiographically positive tests, with or without pain; 19.6 per cent experienced pain but no significant electrocardiographic changes occurred, and 23.9 per cent had no pain and no significant electrocardiographic changes developed. In 3.3 per cent of cases the test was regarded as unsatisfactory.

Group 3 was composed of 108 cases in which there were certain features in the history suggestive of coronary insufficiency and also certain clinical manifestations of a doubtful or contradictory nature. In some cases angina of effort was present or absent under identical circumstances. In other cases the location of the pain in the chest had no relation to the sternum and had no typical extension. In some cases the psychoneurotic makeup of the patient together with the bizarre location of the pain in the chest and its unusual duration in a paroxysm aroused suspicion of its psychosomatic origin. In this group of patients the development of significant electrocardiographic changes during the period of deprivation of oxygen had the greatest value because of the doubtful diagnosis.

Of the 108 patients, 19.5 per cent had electrocardiographically positive tests, with or without pain; 18.5 per cent had pain but no significant electrocardiographic changes occurred, and 50 per cent had no pain and no significant electrocardiographic changes developed. In 12 per cent of patients the test was regarded as unsatisfactory.

Group 4 was composed of 82 patients who gave a history which had few if any features of a true anginal syndrome. The apprehensive individual who has a recent history of pain around the heart and is fearful of serious heart disease is representative of this group. In the opinion of the clinician there was little evidence to support the patient's suspicion.

Of the 82 patients, 1.2 per cent had an electrocardiographically positive test. Although the clinician recognized that the changes ordinarily would be regarded as indicative of coronary insufficiency, he maintained

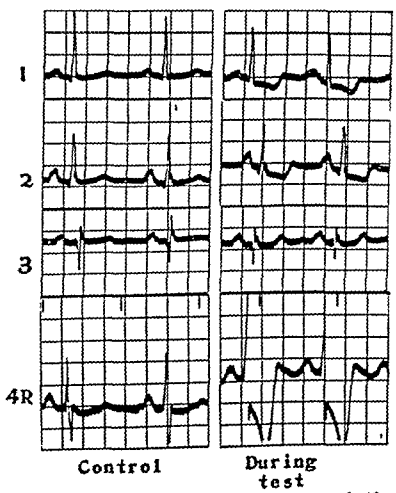

Fig 1.—The patient was a man aged 49 The history was compatible with the diagnosis of angina pectoris. Ten minutes after inhalation of the mixture of 10 per cent oxygen and 90 per cent nitrogen was begun he complained of mild pain in the chest The electrocardiogram designated "During test" was taken at this time The depression of the ST segment in lead 4R indicates coronary insufficiency (criterion 1, Levy).

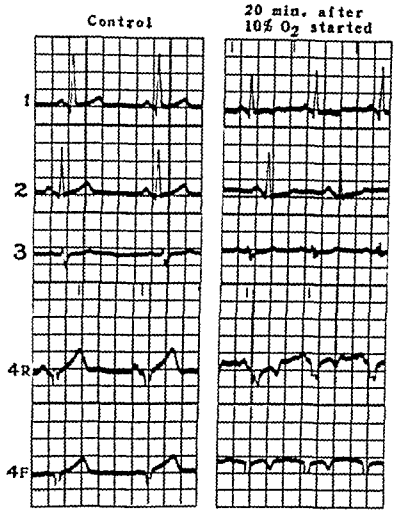

Fig. 2.—The patient was a man aged 50 The history was compatible with the diagnosis of angina pectoris Twelve minutes after inhalation of the mixture of 10 per cent oxygen and 90 per cent nitrogen was begun he complained of a sensation of mild pressure in the sternal area of the chest The complete reversal in the direction of the T wave in leads 4R and 4F indicates coronary insufficiency (criterion 3, Levy).

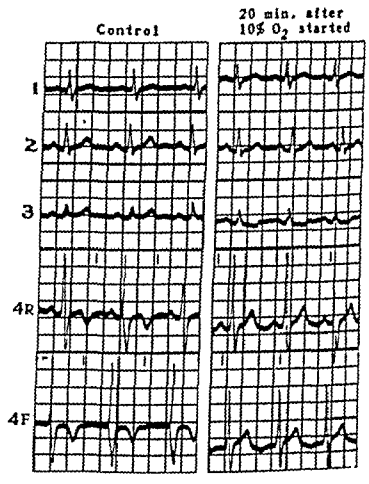

Fig 3 —The patient was a man aged 42 The history was compatible with the diagnosis of angina pectoris. No pain in the chest occurred during the period of oxygen deprivation The complete reversal in the direction of the T wave in leads 4R and 4F indicates coronary insufficiency (criterion 3, Levy).

5 Miss Bess Tews and her associates gave technical assistance in performing the anoxia tests.

his original diagnosis of myalgia of the chest wall. Eleven per cent of patients had pain but no significant electrocardiographic changes occurred, and 76.8 per cent had no pain and no significant electrocardiographic changes developed. In 11 per cent of cases the test was regarded as unsatisfactory (tables 1 and 2).

Unfavorable Reactions.—In general, the same type of unfavorable reactions were encountered in our patients as were reported by Levy and his associates [6] and by Burnett and his associates.[7] In 25 of the 39 cases in which an unfavorable reaction occurred, the test was regarded as unsatisfactory.

Nine patients had vasovagal reactions characterized by a fall in blood pressure associated with slowing of the pulse rate and, in some instances, with cold sweat, pasty color and the appearance commonly seen in shock. Three patients had nausea and, as a result, the test was discontinued. The test was discontinued when 4 additional patients complained of severe generalized discomfort or requested that the procedure be interrupted.

Within six minutes after the test was started, 1 patient became restless and complained of a "huge head" and nausea. The blood pressure dropped to 70 mm. of mercury systolic and 40 mm. diastolic. A questionable momentary loss of consciousness occurred and a few convulsive twitches were noted.

Loss of consciousness occurred in 3 cases. One of these patients fainted and another was "beginning to lose consciousness" when 100 per cent oxygen was introduced. In the third case the reaction was associated with development of arrhythmia and cardiac arrest for more than three seconds.

In 1939 Levy, Bruenn and Russell [8] reported that in their experience with the anoxia test arrhythmia had not occurred and that "ventricular premature contractions present in control records in several instances disappeared with the induction of oxygen want."

Our own results are at variance with these findings. One patient stated that with exercise his heart became irregular, and frequent ventricular premature contractions developed while he was breathing the mixture containing 10 per cent oxygen. This finding is interesting but not representative. In 5 other cases the number of premature contractions increased during the test, and in 8 more cases this type of arrhythmia persisted unchanged throughout the period of oxygen want. In cases in which the only cardiac irregularity was of the extrasystolic type the test was carried through to a satisfactory termination. Nodal premature contractions developed in 1 case. Nodal rhythm developed during the test in 2 cases. In 1 of these the altered rhythm started twelve minutes after the test was begun. The heart rate had increased from 62 to 98 beats per minute during the twelve minutes and dropped to 44 at the onset of nodal rhythm. The administration of 100 per cent oxygen was begun immediately and normal sinus rhythm was resumed. In the second case the onset of nodal rhythm was attended by the clinical picture of shock; that is, there was loss of consciousness momentarily and a blood pressure reading could not be obtained.

In 2 cases there was complete cardiac arrest, which in 1 case lasted for more than three seconds (fig. 4) and in the other for exactly four seconds. The first patient momentarily lost consciousness.

The 4 cases in which nodal rhythm or cardiac arrest developed during the test were reviewed. No characteristic which was peculiar to these from the standpoint either of the histories or of the physical status could be defined. The clinical evidence of angina pectoris was equivocal and the element of anxiety was large, perhaps unusually so. One of the 2 patients who had cardiac arrest had had a conduction disturbance (wide S wave pattern, bundle branch block) for at least three years. We know of no means of predicting when such a reaction might develop.

TABLE 1.—*Results in 289 Anoxia Tests*

Clinical Classification as to History of Angina Pectoris	Total Cases	No Pain or Significant Electrocardiographic Changes		Pain Without Significant Electrocardiographic Changes		Significant Electrocardiographic Changes Without Pain		Significant Electrocardiographic Changes With Pain		Unsatisfactory	
		Cases	%	Cases	%	Cases	%	Cases	%	Cases	%

THE SIGNIFICANCE OF CHANGES IN THE T WAVE IN THE PRECORDIAL LEADS

In publications concerning the anoxia test prior to June 1942, Levy and his associates [6] had maintained four criteria for electrocardiographic changes constituting a positive test. The first three are expressed in the introductory section of this paper. In 1942, however, they [4] discarded the fourth criterion, with the following statement: "The combination of partial T wave reversal and RS-T deviation of 1 mm. or more in lead 4F as the sole criterion of a positive test was observed in less than 2 per cent of the cases of coronary sclerosis and was found with equal frequency in normal persons. Its use as a sign of a positive reaction has therefore been discontinued."

E., Clark, T. W., and Bruenn, H. G.: The "Anoxemia Test" as an Index of the Coronary Reserve: Serial Observations on 137 Patients with Their Application to the Detection and Clinical Course of Coronary Insufficiency, J. A. M. A. 117: 2113-2118 (Dec. 26) 1941.

7. Burnett, C. T.; Nims, M. G., and Josephson, C. J.: The Induced Anoxemia Test, Am. Heart J. 23: 306-333 (March) 1942.

8 Levy, R. L., Bruenn, H. G., and Russell, N. G., Jr.: The Use of the Electrocardiographic Changes Caused by Induced Anoxemia as a Test for Coronary Insufficiency, Am. J. M. Sc. 197: 241-247 (Feb.) 1939.

Our experience confirms the wisdom of this revision of criteria, since the fourth one alone was satisfied in only 4 of our cases. In 2 of these cases the clinical evidence was essentially positive for angina pectoris, in 1 equivocal and in 1 essentially negative.

The significance of partial inversion of the T wave in lead 4F with slight segmental deviation is related closely to the more general problem of the significance

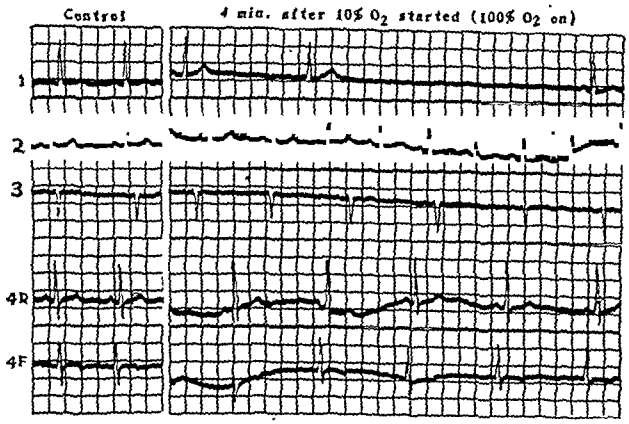

Fig. 4.—The patient was a man aged 41. The history afforded only highly equivocal evidence of angina pectoris. One of the types of cardiac arrhythmia that sometimes develops during periods of oxygen deprivation is shown in lead 1 of the electrocardiogram taken four minutes after inhalation of the mixture of 10 per cent oxygen and 90 per cent nitrogen was begun. The period of asystole lasted 3.4 seconds. Momentary loss of consciousness occurred. The diagnosis remained uncertain.

of alteration of the T wave in the precordial leads. As a positive finding Levy has retained among his criteria complete reversal of the T wave in lead 4F regardless of associated RS-T segment deviation in this lead. For this reason data concerning changes in this wave are important. Certain findings in the present series of tests are interesting, but their significance is mitigated by the diagnostically indeterminate nature of the related clinical material.

Diminution in the height of the T wave in lead 4F as a result of the anoxia test is recognized as a frequent occurrence in individuals who have a normal cardiac reserve. This same observation may be made relative to lead 4R. It seems probable that when the initial height of the T wave in the precordial lead is only 2 to 4 mm., the decrease in voltage that normally occurs during periods of oxygen deficiency might be sufficient to reduce the T wave to, or slightly below, the isoelectric line.

The 8 cases in our series in which the major change in the electrocardiogram during the test was of this type are grouped in column 1, table 3. Seven cases in which the T wave changes in the precordial leads were of comparable degree but were opposite in direction are grouped in column 2 of the same table. In these cases a slightly negative T wave in lead 4R or 4F became almost isoelectric or an upright T wave in these same leads increased in voltage without attendant segmental deviation. The 12 cases in which there was complete reversal of the direction of the T wave in lead 4F without other significant electrocardiographic change are grouped in columns 3 and 4.

The results of the tests listed in columns 1 and 2 were considered to be negative electrocardiographically, according to the criteria of Levy, whereas the results of those in columns 3 and 4 were considered to be positive.

This analysis suggests that a slight increase in height or decrease in negativity of the T wave in leads 4R and 4F more frequently is associated with a history compatible with the presence of coronary insufficiency than is a reduction in the height of this wave to the isoelectric level. We are not concerned with explanations of this observation and record it only because it may be significant if confirmed by further experience.

THE COMPARATIVE VALUES OF PRECORDIAL LEADS

Throughout this series of tests, as mentioned previously, we used both lead 4R and lead 4F. Since Levy and his associates [9] reported only their findings with lead 4F, however, changes in lead 4R were disregarded in determining whether the results of a test were positive or negative. As a matter of fact the results, regardless of which lead is used, are fundamentally the same, as illustrated by the fact that only four of our tests showed significant changes in lead 4R and not in lead 4F and only two tests showed the reverse situation.

INSTANCES OF STRIKING SEGMENTAL ELEVATION

While depression of the RS-T segment, especially in leads 4R and 4F, was the commonest type of change in the positive test, striking elevation of this segment occurred in 4 cases. In 3 of these, elevation of the RS-T segment was most pronounced in lead 3 and was accompanied by segmental depression in lead 1 (fig. 5).

THE EFFECT OF ALTITUDE AND OTHER VARIABLES

In connection with inspiration of oxygen-nitrogen mixtures, two questions pertaining to the physiologic state of the body arise. The first question, which is of practical interest, concerns the effect of geographic increase in altitude. The second question, which is more theoretical in nature, concerns determination of the pressure altitude for a person breathing air which is equivalent to the pressure altitude for a person breathing an oxygen-nitrogen mixture at a constant altitude.

In spite of various prediction formulas for averages, there are no absolute rules for determination of an individual's average alveolar partial pressure of oxygen in an anoxia test of short duration. There is considerable individual variability both in the initial alveolar

TABLE 3.—*Changes in T Wave in Precordial Leads*

Clinical Classification as to History of Angina Pectoris	Column 1 Low Amplitude; T 4R or T 4F Decreased in Height	Column 2 T 4R or T 4F Increased in Height Without Change in Direction	Column 3 Complete Reversal of Upright T 4F	Column 4 Complete Reversal of Inverted T 4F

Group 4, essentially negative	6	..	1	..

partial pressure of carbon dioxide and in the rate and extent of lowering of this pressure. It must be emphasized that the test is individualized and of such short duration that respiratory equilibrium is not present.

The alveolar situation always must conform to the law of partial pressures. When applied to the alveoli, this law reads as follows: $B = p\,O_2 + p\,CO_2 + p\,H_2O + p\,N_2$, in which B designates barometric pressure, and $p\,O_2$, $p\,CO_2$, $p\,H_2O$ and $p\,N_2$ designate partial

9. Levy, Williams, Bruenn and Carr.[6] Levy, Patterson, Clark and Bruenn.[8] Patterson, Clark and Levy.[4]

pressures of oxygen, carbon dioxide, water vapor and nitrogen respectively. The partial pressure of water is assumed to be constant at 47 mm. of mercury. If the ratio of carbon dioxide lost to oxygen absorbed in the alveoli is assumed to be 1 and the person is assumed to be in nitrogen equilibrium, the preceding equation can be written as follows: $B = p\,O_2 + p\,CO_2 + 47$

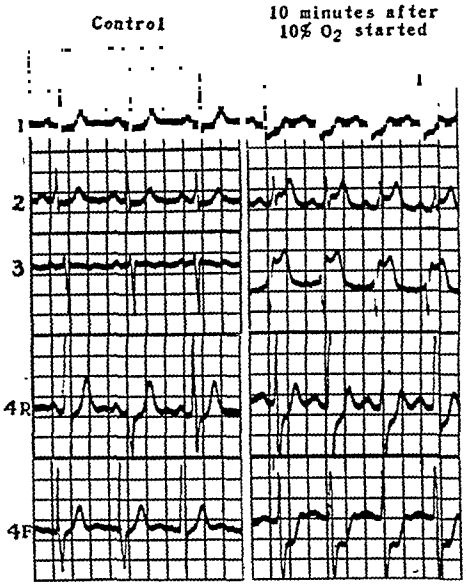

Fig. 5.—The patient was a man aged 38. Six days prior to examination recurring episodes of pain in the chest suggestive of severe coronary insufficiency had occurred. The routine electrocardiogram did not afford satisfactory evidence of recent infarction. Seven minutes after inhalation of the mixture of 10 per cent oxygen and 90 per cent nitrogen was begun the patient complained of slight pain in the left elbow. The electrocardiogram taken ten minutes after the test was begun is of particular interest because the changes recorded simulate those associated with acute infarction of the posterior portion of the left ventricle.

$+ f\,N_2\,(B - 47)$, in which $f\,N_2$ designates the volumetric fraction of nitrogen in the dry mixture.

Unfortunately the alveolar respiratory quotient cannot be predicted during the early respiratory response to anoxia, and as the partial pressure of nitrogen in the lungs is changed exact nitrogen equilibrium will not be present. It may be noted that when the alveolar respiratory quotient is below 1 the partial pressure of nitrogen is higher than $f\,N_2\,(B - 47)$ but that in the early anoxic response the alveolar quotient is likely to be unity or higher.

We think that the preceding alveolar equation is workable in its simple form and that it does not commit one to accurate predictions. It is apparent that, if the percentages of oxygen and nitrogen are fixed in the inspired dry mixture, the main determinants of the partial pressure of oxygen in the lungs are the barometric pressure and the partial pressure of carbon dioxide in the alveoli. With increases in ground elevation or higher altitudes, the barometric pressure would be decreased, and even though the pressure of carbon dioxide of individuals living at higher altitudes normally would be lower at first, the reaction to the test theoretically and practically would be more severe. When low alveolar partial pressures of oxygen, which are encountered when a dry mixture of 10 per cent oxygen and 90 per cent nitrogen is inspired, are related to the oxygen dissociation curve, they fall on the very steep part of the curve.

In addition to the fact that the alveolar partial pressures of oxygen that are encountered are in a critical range, there is also a possible increase in p_H of the blood coincident with increased ventilation of the lungs. This additional variable increases the difficulty of predicting the saturation of hemoglobin with oxygen from the dissociation curves of oxyhemoglobin and alveolar oxygen tension.

When these factors are considered, the deduction can be made that the extent of anoxemia among individuals inspiring the same mixture at the same barometric pressure would differ considerably. This deduction has been confirmed experimentally by Barach and others.[2] We believe that this variation in anoxemia, which cannot be controlled in the test, is one of the factors which determines whether the result will be positive or negative.

The second problem, that is, determination of the exact pressure altitude for a person breathing air which is equivalent to the pressure altitude for a person breathing a mixture of 10 per cent oxygen and 90 per cent nitrogen at a constant altitude, is somewhat conjectural if it concerns an individual rather than a group. This problem is not an integral part of this paper but rather it is of general interest. Excellent observations on the alveolar partial pressures of oxygen and carbon dioxide at various lowered barometric pressures have been made. The alveolar partial pressures of oxygen obtained when individuals have been taken rapidly from ground level to pressure altitudes of from 18,000 to 22,000 feet closely approximate those obtained when individuals at ground level have breathed a mixture of 10 per cent oxygen and 90 per cent nitrogen for a short period of time.

COMMENT

The clinical material analyzed in this report included many cases in which the existence of coronary insufficiency was not established or excluded. Hence any attempt to derive evidence for the definition of criteria for an electrocardiographically positive test is unwarranted. Evidence favoring the accuracy of Levy's criteria may be found, however, in the fact that electrocardiographic changes that satisfied one or more of his criteria developed in a high percentage of cases in which the clinical data favored the diagnosis of angina pectoris. Positive electrocardiographic changes occurred in only 1 case, in which the clinical evidence offered practically no support for the diagnosis of angina pectoris.

Our experience with pain as the sole expression of a positive test contrasted with our experience with electrocardiographic changes. In 11 per cent of 82 cases in which the histories were essentially negative for angina pectoris there was pain without significant electrocardiographic changes during the period of oxygen deprivation; in 19.5 per cent of 92 cases in which the histories were essentially positive there was pain without significant electrocardiographic changes. The [illegible] of cases in which the history was [illegible] and in which pain developed affords minimal grounds for relying on pain as an indication of coronary insufficiency. Levy and his associates suggested that the time of appearance of pain was considerably earlier in cases in which the test was positive electrocardiographically than in those in which it was negative. We have not confirmed this observation (table 4).

We agree with Levy and his associates[4] that "the successful use of pain as an index will depend upon the observer's ability to differentiate it from the minor discomfort of an apprehensive subject." Although pain as an index of diminished coronary reserve may be

helpful if used discreetly, this is not the type of evidence which primarily is being sought in oxygen deprivation studies. A full account of the subjective reactions of the patient is available before the anoxia test is undertaken. The subjective reactions of the patient to the test always must be evaluated in the light of knowledge concerning his temperament. If an individual of stable temperament complains of pain during the test, the ascription of his pain to coronary insufficiency is usually justifiable. If a patient who has a psychoneurotic temperament complains of distress, it may be justifiable to attribute his discomfort to extracardiac factors. The validity of these conclusions depends on the discriminating judgment of the clinician. When the positive or negative result of an anoxia test, however, is determined by the clinician's evaluation of the subjective reactions of his patient, then the test ceases to supply a novel type of information. Accuracy in the diagnosis of angina pectoris always has been dependent on the discriminating judgment of the clinician.

Consideration of this series of cases in which the diagnosis of angina pectoris was not established before the anoxia test was performed provided information concerning its usefulness as a diagnostic adjunct. One assumption must be made; that is, a positive test affords conclusive evidence of coronary insufficiency. The majority of the tests in which significant electrocardiographic changes occurred were performed in cases in which the histories were regarded as highly suggestive of angina pectoris. However, if the test had not been done, the clinician would have retained in most cases some reservation concerning the accuracy of the diagnosis. Any physician who has imposed on an otherwise healthy person a restricted program of activities and then has been harassed by a lingering doubt concerning the accuracy of his diagnosis of coronary sclerosis would value the confirmatory evidence of a positive anoxia test.

TABLE 4.—*Average Time of Appearance of Pain*

Clinical Classification as to History of Angina Pectoris	Significant Electrocardiographic Changes Absent		Significant Electrocardiographic Changes Present	
	Time, Min.	Cases	Time, Min.	Cases
Group 2, essentially positive.....	8	17	9	33
Group 3, equivocal.....	8	18	9	15
Group 4, essentially negative....	6½	9		

What is the value of the test in which the results are negative? Burnett and his associates [7] stated that "since the anoxemia test is designed to furnish objective evidence of coronary insufficiency, a negative or 'normal' response in a patient who presents equivocal evidence of coronary disease adds little to the diagnosis and may further cloud the clinical picture." Levy and his associates repeatedly have warned against the acceptance of negative results as evidence of adequate coronary circulation. Failure to recognize this well established principle will lead to confusion and to incorrect diagnosis. Even with this knowledge it is difficult on certain occasions to resist the temptation to reassure the patient and ourselves that coronary insufficiency does not exist because the anoxia test was negative.

SUMMARY AND CONCLUSIONS

The anoxia test was performed in 289 cases, according to the method established by Levy. In 282 instances the test was performed in cases in which some clinical evidence of angina pectoris existed, although in most of these cases this diagnosis could not have been made on the basis of clinical evidence alone. The results were electrocardiographically positive in 71 of the 282 cases (25 per cent).

Of the 92 cases in which the history was suggestive of angina pectoris, the test was electrocardiographically positive in 53.2 per cent. In 19.6 per cent of cases pain was experienced but there were no significant electrocardiographic changes. In 23.9 per cent of cases the results of the test were completely negative. In 3.3 per cent of cases the test was unsatisfactory.

Of the 108 cases in which an equivocal history of angina pectoris was obtained, the test was electrocardiographically positive in 19.5 per cent. In 18.5 per cent of cases there was pain but there were no significant electrocardiographic changes. In 50 per cent of cases the results of the test were completely negative. In 12 per cent the test was unsatisfactory.

Of the 82 cases in which the histories contained few if any suggestions of a true anginal syndrome, the test was electrocardiographically positive in 1.2 per cent. In 11 per cent of cases there was pain but there were no significant electrocardiographic changes. In 76.8 per cent of cases the results of the test were completely negative. In 11 per cent the test was unsatisfactory.

The occurrence of pain unattended by significant electrocardiographic changes during a test does not impress us as an event likely to contribute significantly to the solution of a diagnostic problem.

Twenty-five of 289 tests were regarded as unsatisfactory because one or several unfavorable reactions occurred. In 2 cases in which a brief period of cardiac arrest occurred, the reaction was regarded as dangerous.

In the majority of instances (66.2 per cent) in which the test was electrocardiographically positive, the only significant change consisted of a deviation, usually a depression, of the RS-T segment, totaling 3 mm. or more, in leads 1, 2, 3 and 4F. We think slight increase in height or decrease in negativity of the T wave in lead 4F or 4R more frequently is associated with a history suggestive of angina pectoris than is a depression to the isoelectric or diphasic level of a positive T wave in these same leads. Significant changes occurred in lead 4R and not in lead 4F in only four tests, and in lead 4F and not in 4R in only two tests.

Finally, the following observations concerning the choice of patients to be subjected to the anoxia test are presented in full recognition of the fact that further work in this field may necessitate a revision of opinion.

The anoxia test is not a laboratory short cut to the diagnosis of coronary sclerosis but is a means of substantiating a diagnosis of angina pectoris based on fairly convincing clinical evidence. In support of this conclusion (1) 53.2 per cent of 92 patients who had a history highly suggestive of angina pectoris had an electrocardiographically positive test and (2) of 82 patients who had minimal evidence of coronary disease only 1 had significant electrocardiographic changes during the period of oxygen want.

Use of the anoxia test should be restricted even among acceptable cases to instances in which (1) serious disagreement regarding diagnosis has occurred and (2) the establishment of a definite diagnosis is of such importance that acquisition of all helpful evidence is imperative. In some cases the presence of disease of the coronary arteries is of greater significance than in others. For a comparatively young person whose occupation entails much physical exertion or

nervous tension a restricted program of activities is a greater hardship than for an elderly person.

When use of the anoxia test is restricted to individuals selected in compliance with the foregoing standards, the possible danger to the life of the patient and the expenditure of time, effort and materials by the clinician are justifiable in view of the value of the information that can be obtained.

PROLONGED BLOOD CONCENTRATIONS AFTER ORAL ADMINISTRATION OF MODIFIED PENICILLIN

HENRY WELCH, PH.D.
CLIFFORD W. PRICE, A.B.
AND
VELMA L. CHANDLER, B.S.
WASHINGTON, D. C.

It appears from the investigations made to date that successful oral administration of penicillin may hinge on complete neutralization of the acidity of the stomach plus a relatively slow release of this drug from some chemical which adsorbs it readily. In 1929 one of us,[1] following the studies of Gross,[2] utilized magnesium hydroxide in the purification of diphtheria toxin. It was noted at that time that this metallic hydroxide selectively adsorbed diphtheria toxin quite firmly in the presence of proteins. After adsorption vigorous treatment was required for the release of the exotoxin from the magnesium. Other metallic hydroxides acted similarly but appeared to be less effective in their binding power. However, in all cases selective adsorption occurred rapidly, resulting in a relatively pure diphtheria toxin.

On the basis that possibly penicillin, a biologic excretory product of a mold, might behave similarly, several manufacturers' products were treated with aluminum hydroxide gel U. S. P. and with magnesia magma U. S. P. by adding 30 cc. of the former and 20 cc. of the latter dropwise with constant agitation to 100,000 units dissolved in water. The penicillin and metallic hydroxides were then centrifuged at high speed and the penicillin concentration in the supernatant liquid determined.

In the case of the aluminum hydroxide, approximately 50 per cent of the penicillin added to it remained adsorbed on the sediment, while approximately 25 per cent of the penicillin remained adsorbed on the sedimented magnesium hydroxide. Both the aluminum and the magnesium hydroxide sediments were washed five times with distilled water. After three washings 27 per cent of the penicillin remained adsorbed on the aluminum hydroxide. Less than 0.5 per cent of the remaining penicillin was removed with the next two washings. However, all penicillin was released from the aluminum hydroxide on washing with buffer at p_H 6.0. It is of interest that after release from the aluminum hydroxide into buffer the penicillin solutions, originally yellow, were water clear and colorless. A similar result is obtained in the purification of diphtheria toxin by adsorption on magnesium hydroxide.

In the case of the magnesium hydroxide, which originally adsorbed approximately 25 per cent of the penicillin added to it, 16 per cent remained after the first washing. Four more washings with distilled water were not successful in removing this adsorbed penicillin. When penicillin was similarly treated with mixtures of aluminum and magnesium hydroxides, approximately 42 per cent of the penicillin was adsorbed. The first two washings with distilled water reduced this to 28 per cent. Practically none of the penicillin remaining was removed by three more washings. The penicillin adsorbed on mixtures of aluminum and magnesium hydroxides was removed from these chemicals on treatment with phosphate buffer, indicating that when penicillin is adsorbed on such mixtures it is preferentially adsorbed by the aluminum hydroxide. From these studies it appeared that penicillin is adsorbed more readily by aluminum hydroxide than by magnesium hydroxide but that magnesium hydroxide is more retentive.

ORAL ADMINISTRATION OF PENICILLIN ADSORBED ON ALUMINUM HYDROXIDE

In preliminary feedings, penicillin treated with aluminum hydroxide was used. Eleven volunteers (laboratory personnel) ingested in one dose 100,000 units of penicillin sodium in 20 cc. of water to which had been added dropwise, with constant agitation, 30 cc. of U. S. P. aluminum hydroxide. In all cases the preparation was given at 10 a. m., two to three hours after breakfast. As far as possible, bloods were taken one-half, one, two, four, seven and twenty-four hours after the penicillin was ingested. All blood samples were held in the refrigerator for twenty-four hours, following which the serums were removed by centrifugation and tested for penicillin activity by a series dilution technic[3] using Bacillus subtilis as the test organism. The standard used was the Food and Drug Administration calcium salt reference standard.[4] One unit of this standard invariably causes inhibition of the B. subtilis strain used in a dilution of 1:128. In chart 1 the results are presented in a composite curve. The number of determinations made at each point on the curve are shown. The individual curves followed the same general pattern. It will be noted that within thirty minutes the average concentration of penicillin in the blood was 0.29 unit per cubic centimeter. The average number of units in the serum after one hour was 0.125 per cubic centimeter, but this increased to 0.146 per cubic centimeter in one and one-half hours. This increase was due to the high level of 1 person who showed 0.375 unit per cubic centimeter of serum after one and one-half hours, while the other 3 persons on whom determinations were made at this time interval were 0.06, 0.06 and 0.09 unit per cubic centimeter respectively. At the end of the second hour the average amount of penicillin in the blood serum was 0.05 unit per cubic centimeter. This diminished to an average of 0.02 unit after four hours and to 0.015 unit after seven hours. On an average, the latter concentration was maintained through the twenty-fourth hour. Of the eleven tests made on the twenty-four hour blood samples in this series, 5 persons had concentrations of penicillin equivalent to from 0.03 to 0.045 unit per cubic centimeter of serum. The serum

of the remaining 6 persons showed no activity by the test used, which was set up to measure a minimum of 0.03 unit per cubic centimeter of serum.

As a control, 6 persons were given orally in one dose 100,000 units of untreated penicillin sodium. The results are shown also in chart 1. It will be noted that with untreated penicillin the serum concentrations are considerably lower one-half and one hour after

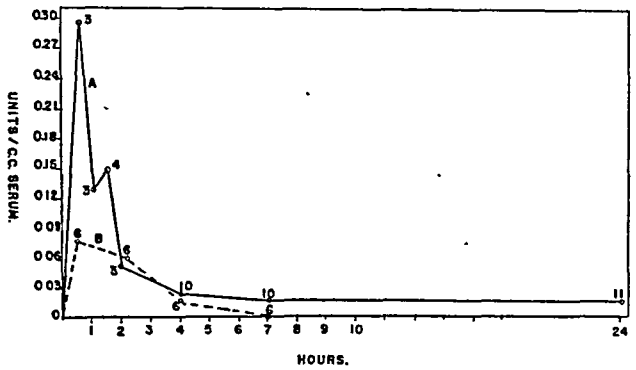

Chart 1.—Composite curves of blood levels following single oral dose of 100,000 units of (*A*) penicillin-aluminum hydroxide and (*B*) penicillin only. Numbers indicate the determination made at each point on curve.

ingestion. No penicillin could be demonstrated in the blood samples collected at the seventh and the twenty-fourth hour. Actually, of the 6 persons tested at the fourth hour 4 failed to show penicillin in their serums. By comparison, in the group given penicillin modified with aluminum hydroxide 5 of the 10 tested showed concentrations of 0.03 unit per cubic centimeter at the seventh hour, and they maintained this concentration through the twenty-fourth hour.

Since serum concentrations of penicillin reached nearly 0.30 unit per cubic centimeter within thirty minutes after ingestion of 100,000 units of penicillin modified with aluminum hydroxide but fell rapidly thereafter (chart 1), it seemed advisable to determine the effect of ingesting the same amount of penicillin at two hour intervals in four equal doses of 25,000 units each. Three million units of penicillin-aluminum hydroxide were prepared as described by adding to each 100,000 units 20 cc. of distilled water and 30 cc. of U. S. P. aluminum hydroxide. The penicillin represented the products of several manufacturers, but all were pooled in the preparation of the modified penicillin. Twenty-one persons were given 25,000 units (12.5 cc.) of the modified penicillin at 10 a. m., 12 noon, 2 p. m. and 4 p. m. Blood samples were obtained from all 21 test subjects one-half hour and twenty-four hours after ingestion. In addition, on 10 to 12 test subjects blood samples were taken two, two and one-half, four, four and one-half, six and six and one-half hours after ingestion and on 5 test subjects eight, twelve, fifteen, eighteen and twenty-eight hours after ingestion. The serum concentration levels of penicillin obtained are presented in a composite curve in chart 2, which shows that within one-half hour after each dose there is a definite increase of penicillin in the blood. After the first dose and subsequent increase in blood concentration of penicillin there is a fall in the concentration to 0.08 unit per cubic centimeter by the second hour, at which time a second dose of penicillin was given. The second dose was followed by an increase in the blood concentration of penicillin, as were the third and fourth doses. In the composite curve the average blood concentration level of penicillin one-half hour after the fourth dose is definitely increased over that obtained one-half hour after the first dose. It should be noted that after the first half hour the concentration of penicillin in the blood did not drop below approximately 0.08 unit per cubic centimeter until after the eighth hour (no penicillin was given after the sixth hour). From the eighth hour until the twelfth hour a concentration of 0.06 unit or more per cubic centimeter of blood was maintained. Between the twelfth and fifteenth hours the concentration dropped to 0.036 unit per cubic centimeter and this level was maintained through the twenty-eighth hour. By contrast, 6 persons given 100,000 units of untreated penicillin sodium, 25,000 units every two hours, had an assayable level for from seven to eleven hours.

Five persons were given, orally, penicillin modified with magnesium hydroxide prepared by adding dropwise, with constant agitation to each 100,000 units of penicillin sodium in 28 cc. of water, 22 cc. of U. S. P. magnesium hydroxide. Each person in this group was given 25,000 units (12.5 cc.) every two hours until a total of 100,000 units had been used. Blood samples were taken one-half hour and two, four, six and twenty-four hours after the first 25,000 unit dose was ingested. The curves obtained by plotting serum concentrations of penicillin against time were similar to those obtained with penicillin modified with aluminum hydroxide. Four of the 5 persons showed 0.06 unit per cubic centimeter in their serums twenty-four hours after the first dose had been administered. The amount of magnesium hydroxide used caused some laxative effect in 3 of the 5 persons in this series. However, magnesium hydroxide was as effective as aluminum hydroxide in the maintainance of penicillin in the blood after oral administration.

EXCRETION OF PENICILLIN IN THE URINE FOLLOWING MODIFIED PENICILLIN ORALLY

Eleven persons were given in a volume of 50 cc. a single oral dose of 100,000 units of penicillin modified with aluminum hydroxide. All urine was collected for a period of twenty-four hours. On an average, 13.6 per cent of the penicillin ingested was recovered in the urine. Twelve per cent of that recovered was obtained in the first two and one-half hours. The largest amount excreted was 27.3 per cent and the least 5.5 per cent. Penicillin was demonstrated in the urine as late as the nineteenth hour but in low concentrations. Two of the 11 persons under study failed to show penicillin in the urine at the nineteenth

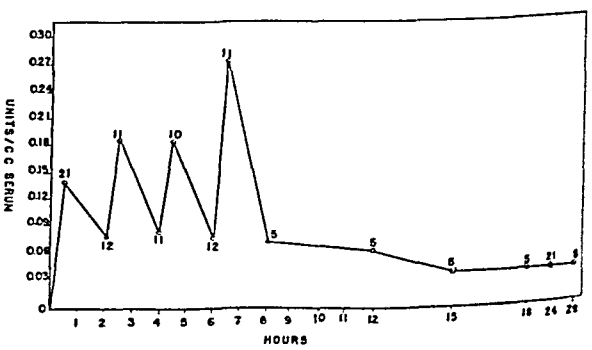

Chart 2.—Composite curve of blood levels following 100,000 units of penicillin aluminum hydroxide given orally in four doses of 25,000 units each at zero, two, four and six hours. Numbers indicate the determinations made at each point on curve.

hour, while the other 9 individuals showed at this time an average total excretion of 47 units. For comparison, the urine excreted after the ingestion of 100,000 units of untreated penicillin sodium was determined in 10 persons. The average total recovery was 6.7 per cent of that ingested, and 6 per cent of this was recovered in the first two and one-half hours. None was recovered after the seventh hour.

The average total excretion over a twenty-four hour period following four oral doses of 25,000 units of penicillin modified with aluminum hydroxide was determined on 11 persons. The average total recovery was 7,245 units (7.2 per cent); the greatest recovery was 15 per cent, and the least 1.2 per cent. The doses of penicillin-aluminum hydroxide were given at zero, two, four and six hours, and urines were collected one hour after each dose and then at irregular periods thereafter. The average amount of penicillin excreted by the 11 persons in this group one hour after the first dose was 2,165 units, one hour after the second dose 1,385 units, one hour after the third dose 1,759 units and one hour after the fourth dose 1,187 units.

Since the penicillin-aluminum or penicillin-magnesium hydroxide mixtures may be prepared just before they are administered orally, there is no stability problem involved. After the aluminum hydroxide-penicillin and the magnesium hydroxide-penicillin are prepared, their stability seems to be similar to that of penicillin sodium in distilled water, since at refrigerator temperature (10 C.) both mixtures have been found to be stable for at least thirty days.

COMMENT

The mechanism by which relatively high concentrations of penicillin are maintained in the blood following oral administration of penicillin modified with aluminum hydroxide cannot be explained on the basis of the experimental work done to date Certain facts, such as the strong neutralizing effect of aluminum hydroxide on the acid of the stomach, are established. The rapidity with which relatively high concentrations of penicillin may be demonstrated in the blood following a single oral administration of penicillin, modified with aluminum hydroxide, indicates that perhaps there is some absorption of penicillin directly from the stomach into the blood stream. This rapid increase in blood concentration of penicillin is demonstrable following each oral dose of penicillin-aluminum hydroxide. There is some indication at least of an accumulative effect since, as will be noted in chart 2, the concentration levels of penicillin reached after the second and fourth doses are considerably higher than that level reached following the first dose. Furthermore, following the first dose of penicillin-aluminum hydroxide (chart 2) in no instance did the serum concentrations of penicillin fall below what may be considered to be an effective therapeutic level until some time after the twenty-fourth hour, in spite of the fact that penicillin-aluminum hydroxide was not given after the sixth hour. It is suggested that the initial increase in blood concentration of penicillin following each dose of penicillin-aluminum hydroxide is the result of absorption through the walls of the stomach of penicillin which is either unadsorbed or loosely adsorbed on the aluminum hydroxide. Following this the penicillin-aluminum hydroxide passes into the upper intestine, where penicillin is released slowly from the aluminum hydroxide and adsorbed through the walls of this organ, thus reaching the blood stream via the portal system and the liver.

There is some difference of opinion concerning the concentration of penicillin in the blood necessary to exert efficient antibacterial action. It has been pointed out by Fleming,[5] after his studies on penicillin content of blood serum following various doses of this drug parenterally, that "we do not yet know whether it is better to maintain a constant low level of penicillin in the blood or to have a very high level for a short time after injection. . . . Clinically both systems have worked excellently." The oral administration of four doses of 25,000 units each two hours apart of penicillin modified by either aluminum hydroxide or magnesium hydroxide will result in a prolonged level of penicillin in the blood stream. It may be that the level of penicillin maintained by this dosage form will be effective in some diseases, but it can be postulated that in all likelihood it will not be effective in others. Actually, it probably will be necessary to maintain higher penicillin levels in the blood for the same disease in different individuals. However, if it becomes necessary to maintain high levels in the blood for longer periods of time, this may be accomplished by more frequent and larger doses. In preliminary studies with 150,000 units of penicillin-aluminum hydroxide given in six equal doses of 25,000 units each, serum levels of 1.0 to 1.5 units per cubic centimeter have been demonstrated.

SUMMARY AND CONCLUSIONS

A method of oral administration of penicillin modified with either aluminum hydroxide or magnesium hydroxide results in prolonged blood concentrations of this drug.

Blood levels of from 0.03 to 0.19 unit per cubic centimeter may be obtained for as long as twenty-four hours after the administration of 100,000 units in four doses of 25,000 units each. In some persons, serum concentrations of 0.06 unit were obtained thirty hours after the administration of 100,000 units in four doses of 25,000 units each.

Following each dose there is a pronounced increase in the blood concentration level of penicillin, and this blood level may be increased with subsequent doses. Relatively high levels of penicillin may be maintained in blood by increasing the frequency of the doses of penicillin-aluminum hydroxide.

Since the modified penicillin may be prepared at the time of use, no stability problem is involved.

After oral administration of the modified penicillin, relatively small amounts are excreted in the urine. The penicillin is apparently largely inactivated within the body. It appears that some absorption through the stomach wall is obtained followed by further slow absorption from the small intestine.

Because of prolonged penicillin concentrations in the blood following this method of oral administration, this dosage form may have some prophylactic value.

Good Traits.—In human nature good traits go together. To him that hath a superior intellect is given also on the average a superior character; the quick boy is also in the long run more accurate; the able boy is also more industrious. There is no principle of compensation whereby a weak intellect is offset by a strong will, a poor memory by good judgment or a lack of ambition by an attractive personality. Every pair of such supposed compensatory qualities that has been investigated has been found to show correspondence.—Thorndike, E. L.: *Harper Hosp. Bull.* **111**:227, 1920.

THE USE AND ABUSE OF GOLD THERAPY IN RHEUMATOID ARTHRITIS

BERNARD I. COMROE, M.D.
PHILADELPHIA

Unfortunately, some physicians employ gold salts in any type of arthritis; a few begin gold therapy at the first complaint of joint pain. Workers experienced in the care of rheumatic patients agree that gold is of no value in any type of joint disease except rheumatoid arthritis; some have not observed pronounced improvement even in the latter disease. Because of this indiscriminate, frequent abuse of gold salts in many forms of joint disease, the known facts concerning gold therapy in rheumatoid arthritis are discussed here briefly.

There are several important facts concerning gold therapy in arthritis:

1. Gold is of no value in any form of joint disease except rheumatoid arthritis.
2. Gold does not benefit all patients with rheumatoid arthritis.
3. Gold is not the final answer to the treatment of rheumatoid arthritis.
4. Toxic symptoms may appear at any time during this form of therapy.
5. From 10 to 20 per cent or more of patients who have received gold therapy relapse after stopping the drug.
6. Extreme care must be used during gold therapy and the physician must be familiar with the details of such treatment before undertaking this.
7. Injections of certain gold salts in proper dosage may be followed by subjective and objective evidence of improvement in the majority of selected patients with rheumatoid arthritis.

Gold salts are not advisable routinely at the onset of every case of rheumatoid arthritis. Conservative therapy results in some improvement in many patients with this disease when these individuals are followed carefully over a period of five to ten years. If the patient with rheumatoid arthritis obtains no benefit from conservative measures over a period of several months or if he grows steadily worse, gold therapy may be given if the physician is well acquainted with this form of therapy. Gold is still too dangerous for common use by the physician unless he has had special experience in this field.

Most specialists in rheumatic disease no longer believe that there is any specific virtue in the treatment of arthritis by bee venom, chaulmoogra oil, vaccines or sulfur except perhaps as a form of psychogenic therapy. The significance of focal infection in most cases of rheumatoid arthritis is still open to question. It is generally agreed that removal of focal infection by itself will not produce any great amelioration in the symptoms in most cases of rheumatoid arthritis. Fever therapy helps only a small percentage of these patients and the resulting improvement is usually only temporary. This does not apply to short periods of mild physical fever with temperatures up to 100 or 101 F., which may be definitely beneficial to some of these patients. The use of massive doses of vitamin D is still under investigation, but most rheumatologists agree that although some patients with rheumatoid arthritis may be benefited by this form of therapy the improvement is usually only temporary and in many cases disappears when the drug is stopped.

From the Arthritis Clinic of the Hospital of the University of Pennsylvania.

One should always emphasize the necessity of individualizing the program for the care of patients with rheumatoid arthritis. The program generally employed for this disease includes adequate mental and physical rest (with avoidance of emotional upsets if possible); local rest to the involved joints by means of splints when these are indicated; a nourishing, high vitamin, high caloric, anticonstipation diet unless the patient is decidedly overweight; proper physical and occupational therapy; orthopedic care as indicated; removal or treatment of definite focal infection as a general health measure to lessen the load of infection which the individual is carrying, and blood transfusions in some cases and symptomatic care as indicated including analgesics, sedatives and so forth.

Gold has been used as a therapeutic agent for many centuries. It was recommended as a panacea in the eighth century and was advocated in 1500 by Paracelsus together with mercury as an elixir of life. Although inorganic preparations of gold were in use until 1916, many organic compounds have been developed since that time. In 1913 Feldt [1] showed that certain preparations of gold possessed antibacterial properties. In 1927 he also showed that gold compounds were effective against experimentally produced streptococcic and spirochetal infections in mice. Lande [2] and Pick [3] reported on the use of gold preparations in human chronic polyarthritis in that same year. Forestier [4] popularized this form of therapy after he had treated large numbers of arthritic patients with gold preparations.

The Council on Pharmacy and Chemistry [5] has recognized the use of gold preparations only in the treatment of lupus erythematosus. Gold salts have been advocated for pulmonary tuberculosis, epidemic encephalitis, bronchopneumonia, asthma, influenza, migraine, malnutrition, alcoholism, typhoid, septicemia and many other diseases. Gold salts have been suggested as an analgesic, antispasmodic, sedative, hematinic, cardiac stimulant and even for the treatment of neurosis, debility and acute and chronic arthritis. There is no evidence substantiating the great majority of these claims.

Until recently the widespread use of gold was limited by its untoward reactions, the crudeness of the available preparations and the uncertainty of the dose. Because of the supposed beneficial action of gold salts in tuberculosis, Forestier believed that this metal should also be of value for patients with rheumatoid arthritis (which appeared to him to be a chronic wasting disease similar in some respects to tuberculosis).

Experimental animal and human clinical work now suggests that gold may be an important addition to our therapeutic armamentarium. Sabin,[6] Freyberg [7] and others have shown that gold preparations are definitely beneficial in the arthritis produced experimentally in

mice by means of pleuropneumonia-like organisms. Dawson,[8] Freyberg,[9] Boots,[8] Hartung,[10] Cecil,[11] Snyder [12] and others have reported that rheumatoid arthritis in human beings has been definitely benefited by injections of gold. Others are not impressed by the results of gold therapy. Several years ago Bauer [13] observed definite subjective and objective improvement in only 4 of 30 patients treated with gold salts. In his experience these results were no better than the usual treatment with rest, a high caloric, high vitamin diet, analgesics and simple physical therapy. It was his opinion at that time that within ten years gold therapy would go the way of many previous rheumatic remedies and would not be considered the meritorious, antirheumatic remedy that it is hailed today. Other rheumatologists have used gold salts in rheumatoid arthritis "with hopes but with not very high hopes."

In most of the published reports on the use of gold in rheumatoid arthritis the results are very encouraging. Gold therapy at present seems to be the only drug which shows promise of checking the activity of rheumatoid arthritis; it is still imperfect and must be used with care.

Gold seems in some manner to arrest or lessen the inflammatory process in many cases of rheumatoid arthritis. It will not repair damaged cartilage or bone, will not reconstruct joints and will not rehabilitate the arthritic derelict who has crippling deformities and whose arthritis has been burned out after years of activity of the process. The patient who derives the greatest benefit from proper chrysotherapy is the one with active rheumatoid arthritis, preferably in the early stage of his disease. Although gold therapy is most effective in the early stages of rheumatoid arthritis, it frequently relieves pain and stiffness even in advanced cases and is worthy of a trial for such patients if there is still evidence of an active process at that time.

The physician should not use gold salts in any form of rheumatic disease other than rheumatoid arthritis. There is no indication for gold therapy in degenerative joint disease, as our present concept is that this is a process of aging and wear and tear and that there is no inflammatory process within the joints in these individuals. Likewise, gold therapy is of no value in gout, fibrositis, subdeltoid bursitis or specific infectious forms of arthritis.

MODE OF ACTION OF GOLD SALTS IN RHEUMATOID ARTHRITIS

The mode of action of gold salts in rheumatoid arthritis is unknown. Dawson and Hobby [14] have shown that gold salts have active chemotherapeutic properties against hemolytic streptococcic infection in mice comparable to that obtained with the sulfonamides. Hartung found that subcutaneous injections of gold salts were followed by a manifest increase in the bacteriostatic power of the patient's serum against the hemolytic streptococcus. Others have believed that gold acts by stimulating the reticuloendothelial system, but there is no good evidence in favor of this. Leichentritt and his co-workers [15] thought that gold might produce a diuretic effect with loss of tissue fluid and improvement in the joint symptoms. Other workers previously noted improvement in joint symptoms following the loss of fluid from periarticular tissues which accompanied the diuresis from ammonium chloride and mercupurin. Still others have suggested that gold therapy may be a prolonged acting mild shock therapy.

FATE OF GOLD IN THE HUMAN BODY

Although a small amount of gold is excreted through the intestine and the bronchial mucosa, most of it is excreted through the kidneys. Gold enters practically every cell of the body shortly after it is injected, and the greatest concentrations are found in the liver, spleen, kidneys and skin. Gold has been detected spectrographically in aspirated synovial effusions from the knee joints of patients with rheumatoid arthritis who have been treated with gold salts.

Freyberg and his associates [16] found that gold salts are transported in the blood plasma following intramuscular administration. Although the gold values of plasma and urine may vary with the size of the weekly dose injected, these are not directly proportional to this. The blood level of gold usually increases as the amount of gold injected increases. Although daily plasma values for gold may fluctuate somewhat from day to day, these are usually increased after each injection and remain at this higher level or decrease but slightly until the next injection is given.

The physician should bear in mind this large retention of gold. If large doses of gold salts are given (such as 100 mg. at a dose) approximately 20 per cent is excreted per week. During a course of gold therapy 80 per cent of the injected gold apparently remains in the body. This increasing retention of gold is extremely important clinically, as gold may be found in the urine or plasma for many months in diminishing amounts after the last injection of gold. If the weekly injections of gold are continued at a smaller dose, gold disappears from the urine more rapidly. Although gold has been found in the urine for ten months or more following the last weekly injection of 100 mg. of gold salts, when the weekly injections are limited to 50 mg. of the gold salt the urine may show no gold within a period of three months following the last injection. If still smaller doses are used (such as 25 mg. of the gold salt—which is the maximum dose we employ in most instances at present) the urine may show no gold four weeks following the last injecion. Block and Buchanan [17] have devised an extremely accurate and specific photoelectric colorimetric microchemical method for determining gold in biologic tissues and fluids.

There has been much confusion concerning the value of colloidal gold salts. The urine and plasma gold values vary greatly in different patients following the intramuscular or oral administration of colloidal gold

salts. In some instances no gold is found in the plasma or urine after large amounts of colloidal sulfides are given. Others may absorb gold and have urinary plasma values comparable to those seen with the soluble salts of gold. In most persons, however, very low plasma gold concentrations are found following the administration of colloidal gold sulfide; these patients usually excrete very little gold in the urine.

Colloidal gold preparations are not expected to be as effective therapeutically as other gold salts, mainly because of the rapid phagocytosis of the particles of gold by the reticuloendothelial system with insignificant plasma gold concentrations. Although colloidal gold preparations may produce only few and mild toxic reactions, the gold particles are usually removed from the circulation so rapidly that both toxic reactions and favorable therapeutic effects are prevented.

DOSE OF GOLD SALTS IN RHEUMATOID ARTHRITIS

The dose of gold salts used in the treatment of rheumatoid arthritis is still in the experimental stage. The therapeutic effectiveness of gold probably depends on its absorption and its remaining in the circulation until it arrives at the site of action. Gold preparations which my associates and I have found to be of particular value in the treatment of rheumatoid arthritis include sodium aurothiomalate,[18] aurothioglucose,[19] sodium aurothiosulfate and calcium aurothiomalate.

In an attempt to find the optimal dose of gold salts for patients with rheumatoid arthritis, we progressively decreased the amount of gold given each week until we arrived at the following schedule. Although the doses are small, the therapeutic results seem, in the long run, to be approximately as good as with larger individual doses, and relapses of the disease occur much less frequently. With this smaller dose given intramuscularly we have not seen any serious toxic effects in the last hundred patients so treated. It must be remembered, however, that any schedule of dosage for gold salts is still subject to change, as the optimal dose is not yet known and patients vary widely in their tolerance to gold salts.

We give all injections intramuscularly. The following dosage schedule applies to either sodium aurothiomalate or aurothioglucose. The doses are in milligrams of the gold salts. The first four injections are given at intervals of three or four days and consist of 5 mg. each. All subsequent injections are given at weekly intervals. Ten mg. is given for the fifth and the sixth doses and subsequent injections are of 25 mg. The seventh to the fourteenth injections inclusive are of 25 mg. each. If the patient is definitely improving, as evidenced by lessening of his joint pain, swelling and stiffness and reduction in the sedimentation rate, the 25 mg. weekly injections are continued for an additional twenty-four weeks unless any signs of toxicity appear. If the patient has not definitely improved following the first fourteen injections, the weekly dose is increased to 50 mg. and this dose is continued for a total of twelve weekly injections. If improvement is not noted at the end of this time, one should be pessimistic concerning the use of further gold therapy for that particular patient. It is usually futile to repeat the course of gold therapy of those individuals who have had no improvement at all by such a first course of treatment.

If improvement is definitely noted after the first course of gold, a rest period of from six to eight weeks is permitted, during which time no gold is given. If a relapse in the arthritis occurs, gold therapy is begun after a six week period; in other cases the full eight weeks is allowed to elapse before the second course is given, and the entire first course of therapy is repeated.

Such a course of therapy permits the injection of a total of 850 mg. of the gold salt (or 425 mg. of metallic gold). In some cases, when the gold is well tolerated, if improvement continues but the sedimentation rate has not yet become normal a third course of gold is given after an interval of eight weeks following the termination of the second course.

Some workers have advocated that one should give approximately 50 per cent more aurothioglucose than sodium aurothiomalate in order to obtain biologically equivalent effects, as plasma gold concentrations following the administration of aurothioglucose average only 65 per cent of those following a similar dose of sodium aurothiomalate. Clinically we have obtained results from the smaller doses of aurothioglucose which seemed comparable, in the long run, to equal doses of sodium aurothiomalate.

If one uses gold sodium thiosulfate, it is advisable to increase the dosage schedule by one third, as gold sodium thiosulfate contains only 37 per cent of metallic gold as compared with 50 per cent of metallic gold in both sodium aurothiomalate and aurothioglucose. Although many other preparations of gold are available, insufficient work has been published concerning these to permit a final evaluation of their toxicity and clinical effects.

In the treatment of children with rheumatoid arthritis, proportionately smaller doses of gold salts should be given.

PRECAUTIONS DURING GOLD THERAPY

Either the patient or his family should be advised of the possibility of toxic reactions from gold. Any physician wishing to administer gold salts in rheumatoid arthritis must familiarize himself with the early signs of intolerance to this metal. The patient should be questioned and examined before each injection for any signs of toxicity (particularly rash, itching, sore mouth, metallic taste, jaundice, loss of appetite or persisting indigestion). We perform a complete blood count and urinalysis before each injection. Although this may prove unnecessary, a blood count and urinalysis should be performed at least every two or three weeks during the course of gold therapy.

If any evidence of toxicity appears, gold should be stopped at least temporarily. Some of these patients can tolerate injections of gold later.

Absolute contraindications to gold therapy include any history of purpura or agranulocytic angina; moderate or pronounced renal or hepatic disease; pregnancy; hemophilia; severe diabetes mellitus; colitis; severe anemia or any hemorrhagic tendency; severe eczema or chronic dermatitis; severe bronchial asthma, or any serious systemic illness other than the rheumatoid arthritis itself. Psoriasis is not a contraindication to gold therapy, although individuals with rheumatoid arthritis and psoriasis have responded less well than individuals without psoriatic skin lesions.

TOXIC REACTIONS FOLLOWING GOLD THERAPY

The most serious reactions which occur following gold therapy and which fortunately are very infrequent with small doses of gold and proper care are purpura hemorrhagica, severe exfoliative dermatitis, ulcerative enteritis, acute yellow atrophy of the liver, agranulo-

18. Myochrysine is the proprietary name for sodium aurothiomalate.
19. Solganal-B-Oleosum is the proprietary name for aurothioglucose.

cytic angina and aplastic anemia. Although the mortality following the administration of gold salts some years ago reached as much as 3 per cent or more, this has now been lowered to less than 0.5 per cent. Fortunately, we have had no fatalities following the administration of gold salts.

If small doses of gold salts are employed, severe general reactions are usually avoided, but pruritus and urticaria may occur. Less than 10 per cent of patients with rheumatoid arthritis must discontinue the injections of gold permanently because of intolerance to the drug.

The most common cutaneous reactions following gold therapy are erythema, generalized pruritus and urticaria. Almost any type of rash has been reported as a complication following gold therapy, including herpes, exfoliative dermatitis, leukoplakia, lichen planus, papular eruptions, desquamation, morbilliform rash, erythema nodosum and folliculitis.

Pruritus occurs commonly following gold therapy; it may be generalized or localized to one or more parts of the body. Local or general erythema is a frequent complication. Fortunately, exfoliative dermatitis occurs very infrequently. When gold compounds are stopped temporarily, erythema, pruritus and other mild skin lesions usually clear within a few weeks and the gold can in most instances be begun again.

Oral reactions include a metallic taste in the mouth and a sore tongue and gums. Some patients may experience dysphagia, loss of taste, anesthesia of the tongue or even an ulcerative stomatitis or hemorrhagic gingivitis.

Gastrointestinal symptoms are not uncommon following gold therapy and consist mainly of nausea and epigastric distress. Some patients may experience vomiting, colicky abdominal pains and diarrhea. Ulcerative enteritis has been reported occasionally.

Albumin or red blood cells may appear in the urine following gold therapy. Anemia may follow prolonged administration of gold, and occasionally one notes the development of hepatitis or acute yellow atrophy of the liver. Various respiratory, nervous and ocular complications have been observed following gold therapy, but these are usually rather mild. Rarely one sees an iritis or a retinitis following gold therapy. In these cases it is difficult to determine whether the iritis is a part of the general picture of rheumatoid arthritis or whether it has resulted from the gold.

A few patients may complain of additional pains in the joints and a temporary increase in joint swelling and stiffness for twenty-four hours following an injection.

Toxic reactions may appear at any time following the first injection up until several months after the complete cessation of therapy. When toxic complications occur, the most frequent are pruritus, dermatitis, stomatitis and gastrointestinal symptoms, including some change in taste.

PREDICTION AND PREVENTION OF TOXIC REACTIONS

There is no reliable method of predicting which patients will develop signs of toxicity from gold. The factors on which such reactions depend are not known. Patch tests with gold do not adequately reveal sensitivity to this metal. There is no certain method of preventing untoward reactions from gold salts. Various workers have suggested the concomitant use of vitamin B, large amounts of fruit juices, liver extract or niacin, but in most instances such measures have not eliminated the toxic reactions. Once a toxic reaction has developed, this must be treated symptomatically. There is no specific treatment for these.

One should never neglect any symptom which the patient mentions during the course of chrysotherapy, as this may be the early evidence of a toxic reaction. Patients vary greatly in their tolerance to gold salts.

Gold therapy should be stopped when even a mild reaction occurs. Gold should not be administered again until at least several weeks after the complete disappearance of the reaction. When gold therapy is begun again, minimal doses should be given—such as 10 mg. of the gold salt—this being increased cautiously at weekly intervals until 25 mg. has been given as a maximum for any one injection. Gold therapy should not be resumed for any patient who develops agranulocytic angina, purpura hemorrhagica, exfoliative dermatitis, pronounced albuminuria, aplastic anemia or severe jaundice.

RESULTS FOLLOWING THE ADMINISTRATION OF GOLD SALTS

When small doses of gold salts are used, the patient does not usually notice definite improvement until from one to three months of therapy have passed. The first symptom which is relieved is pain in the joints. Following this, the joint swellings become softer and gradually disappear. The patient's general status also improves and his appetite and strength return while his fever slowly subsides.

In patients whose rheumatoid arthritis is still in the early stage with the inflammatory process limited chiefly to the soft tissues, the improvement following cautious administration of gold salts may be amazing. The results following gold therapy are not so spectacular in the more advanced cases when there is pronounced muscular atrophy, cartilaginous erosion and contractions. Even in these patients, however, the inflammatory process may be checked and the swelling and pain may be reduced. Gold therapy does not form the sole treatment of these patients; the whole individual must be treated as well as his joints.

RELAPSES FOLLOWING GOLD THERAPY

Although the incidence of relapses following gold therapy may be as high as 35 per cent or more in some series, a much smaller incidence is noted when gold is given for a prolonged period in smaller individual doses. Although relapses following gold therapy appear most often within six to twelve weeks following the discontinuance of the drug, in some instances these may occur a year or two later.

SUMMARY

Conservative therapy should be used for at least several months for patients with rheumatoid arthritis before employing gold salts, except those individuals with a rapidly progressing form of the disease. Some workers employ gold salts at the onset of rheumatoid arthritis because results are better in the early cases. Gold salts should not be used in any form of joint disease except rheumatoid arthritis.

One should never insist that any patient with rheumatoid arthritis receive gold therapy because of the possibility of toxic reactions and because gold therapy is not effective in all patients with rheumatoid arthritis; relapses occur in some of these patients when gold is stopped.

THE IMPORTANCE OF DETECTING TUBERCULOSIS IN CHILDREN

J. A. MYERS, M.D.
F. E. HARRINGTON, M.D.
MINNEAPOLIS
AND
E. GARCIA SUAREZ, M.D.
SANTIAGO, CHILE

Children infected with tubercle bacilli under the age of 12 years occasionally develop the acute reinfection type of tuberculosis, such as miliary disease, pneumonia, meningitis, pericarditis, pleuritis, peritonitis and synovitis. During this age period the chronic reinfection type of disease occasionally develops in the extrathoracic organs such as the bones and joints, but the lungs are involved with great rarity. The reinfection type of chronic pulmonary tuberculosis begins to make its appearance among tuberculin reactors in the early teen ages and increases in frequency with the decades. Since this fact was established the previous enthusiasm for examination of school children has waned; indeed, in some places such work has been abandoned. This is an extremely unfortunate situation and is without practical or scientific foundation.

Every child who reacts to tuberculin has primary tuberculosis (tuberculous infection). This disease begins with the first focalization of tubercle bacilli by neutrophils. From this stage it is a matter of reinfections and the like which determine whether the disease will incapacitate or kill. Illness and death from tuberculosis always begin with the simple and apparently harmless infection, just as "a journey of a thousand miles begins with a single step." To refuse or neglect to find the infected child and conduct the necessary procedure in his behalf in any community is to ignore or overlook an important phase of tuberculosis work.

The finding of primary tuberculosis (tuberculous infection) in a child invariably establishes two important facts: 1. Usually a contagious case has been in the child's environment. (Obviously the infected person should be sought, if still alive, and be prevented from spreading tubercle bacilli.)

2. The child has at least lesions of primary tuberculosis containing living tubercle bacilli. Moreover, his tissues have become so sensitized to tuberculoprotein that this substance is now a deadly poison to them. The sensitivity makes reinfections from exogenous or endogenous sources far more dangerous to him than was the first infection; therefore physicians, public health workers and parents must be constantly on guard for the destructive type of lesions in any one of many parts of his body.

The toll of primary tuberculosis is far greater than is generally realized. Bogen [1] made a painstaking analysis and concluded that approximately 50 per cent of infected persons at some time have clinical lesions. Not all who develop such lesions die from them—many are not even incapacitated. Nevertheless, the toll in morbidity and mortality is significant. Indeed, in parts of the world where all adults are infected, 25 to 30 per cent of the total number of deaths have been reported as due to tuberculosis.

Since infection with tubercle bacilli ultimately carries such a high toll it is fortunate that a simple, harmless, inexpensive but highly specific and accurate test is available to determine its presence. There is no phase of the examination for tuberculosis which provides as much specific and accurate information for so many people as the tuberculin test. We are able to inform every reactor that primary lesions containing living tubercle bacilli are present. The only exception is that when all bacilli die sensitivity of the tissues lingers for a time before it completely disappears. Every nonreactor can be told that he does not harbor living tubercle bacilli. The two exceptions are (1) during the preallergic stage and (2) for a short time before death in both acute and chronic forms of the disease. The tuberculin test is the only phase of the examination that is valuable in both a positive and a negative way. All other phases such as auscultation and microscopic and x-ray inspections are helpful when positive findings are revealed, but negative results do not rule out tuberculosis.

We have previously stated [2] that by the tuberculin reaction one obtains the best criterion of the tuberculosis situation in a community with a stable population. It promptly and accurately detects persons in all ages of life who have lesions containing living tubercle bacilli in their bodies. As all tuberculin reactors have been exposed directly or indirectly to contagious cases of tuberculosis, the test provides much information as to the number of such cases which have been allowed to exist in a community. Moreover, when properly administered periodically it is our best criterion as to the effectiveness of tuberculosis control in any community. Obviously an increase in infection attack rate indicates that the control measures have not been satisfactory, whereas a significant decrease is excellent evidence that effective work has been done. Wherever large numbers of contagious cases of tuberculosis are permitted to exist among people or animals without adequate isolation or control, a high percentage of children develop primary tuberculosis. Moreover, testing children gives one an idea of the potential clinical tuberculosis load of the future. If children are not being infected in large numbers, in all probability not many adults are being infected and reinfected from exogenous sources—obviously, the lower the incidence of infection and reinfection, the lower the morbidity and mortality from clinical tuberculosis.

In 1926 the tuberculin test was administered to children in Minneapolis grade schools, which were selected on the basis of their distribution throughout the city.[3] The percentage of reactors ranged from approximately 15 at the age of 6 to 70 at the age of 14 years (chart 1) with an average of 47.33 (chart 2). Thus, the infection attack rate had been so high that nearly one half of the grade school children had primary tuberculosis (tuberculous infection). The explanation for this unfavorable situation was evident. For example, in 1921, when the population of the city was 384,571, the tuberculosis mortality rate was 115 per hundred thousand (443 deaths). The municipal and county sanatoriums had a combined bed capacity of 250. In 1924 the municipal sanatorium, with 130 beds occupied by advanced cases, was abandoned because the county sanatorium had increased its capacity and was thought

sufficient to care for all contagious cases. Nevertheless in 1925, when the total bed capacity in the county sanatorium was 417, when a small private hospital was operating to capacity and when a number of city patients were being housed in the state sanatorium and the veterans' hospital, there still remained an average of 120 patients on the county sanatorium waiting list. There was also a large number of tuberculous patients who refused to apply for institutional care and who remained in their homes until death. Treatment in the homes was not conducted according to modern methods; that is, there was little or no attempt to isolate patients and protect their associates against bacilli. Moreover, most patients had such advanced disease when detected that it was impossible to convert them from the contagious to the noncontagious stage.

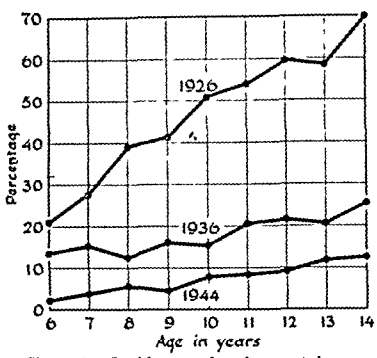

Chart 1.—Incidence of primary tuberculosis (tuberculous infection) among children in the same schools at intervals of approximately one decade.

While a pasteurization ordinance was in effect, there were numerous dairy products consumed by the citizens which had not been pasteurized. At that time only a few counties in the state had been accredited with reference to tuberculosis in cattle. Thus, tubercle bacilli were rife, as was reflected in the incidence of primary tuberculosis (tuberculous infection) among children.

With the continuance of this situation satisfactory control of tuberculosis could not be anticipated; therefore the program was intensified and methods were improved. Between 1925 and 1936 the total bed capacity at the county sanatorium reached 750 (60 of these beds were for children with primary tuberculosis and therefore did not assist in controlling contagion). Thus many more contagious cases could be isolated than in the previous decade. The Lymanhurst School and Health Center abandoned its treatment division for children with primary tuberculosis and concentrated its efforts on epidemiology. Large numbers of school children were tested with tuberculin, and the sources of the reactors' infections were sought among their adult associates. Many contacts of contagious cases were examined periodically. During this period all of the eighty-seven counties were accredited, so that by 1935 the state was designated a modified accredited area with reference to tuberculosis in cattle. By 1936 the tuberculosis mortality had dropped to 34 per hundred thousand (170 deaths). Thus, during this decade the number of tubercle bacilli which might be ingested or inhaled by children presumably was much decreased.

In 1936 we were desirous of obtaining tangible evidence [4] of the success of the methods employed during the past decade. Therefore we administered the tuberculin test to the children in the same schools as in 1926. The incidence of the first infection type of tuberculosis, as manifested by the intracutaneous test (Mantoux), ranged from approximately 14 per cent at the age of 6 to 26 per cent at the age of 14 years (chart 1) with an average of 18.9 (chart 2).

4. Harrington, F. E.; Myers, J. A., and Levine, N. M.: Significance of the Tuberculin Test, J. A. M. A. **108**: 1309 (April 17) 1937.

While approximately 1 of each 2 children had primary tuberculosis in 1926, it was present in only 1 in each 5 in 1936; thus, the potentialities of clinical tuberculosis during adulthood were definitely decreased.

Although the result of testing in 1936 denoted good progress in tuberculosis control, the situation was still far from satisfactory. Therefore the program was again intensified. Between 1936 and 1944 many patients with contagious and precontagious pulmonary tuberculosis were admitted to the sanatorium. The public had become so tuberculosis conscious that large numbers of apparently healthy persons were examined. Collapse therapy was employed extensively; in fact, one general hospital had set aside a division for chest surgery, and many patients with minimal and early moderately advanced tuberculosis were treated with ambulatory artificial pneumothorax, which prevented a sizable number from becoming contagious and converted others from the contagious to the noncontagious stage. The Minneapolis General Hospital had established a special chest disease service which was used as a clearing house for persons with pulmonary lesions suspected of being tuberculous. Those found to be in need of treatment for this disease were advised to transfer to the sanatorium. An advance step taken during this period consisted in quarantining incorrigible contagious cases. They were apprehended by the police department when necessary and committed to the sanatorium for as long as was deemed necessary by the commissioner of health and the sanatorium staff.

The testing of cattle throughout the state continued and the reactors, the total number of which was small, were killed. This was true also in adjacent states which might transport dairy products to the city; therefore it became extremely rare for a child or an adult to be infected with the bovine type of tubercle bacillus. In 1942, when the population of the city was 492,370, the tuberculosis mortality had dropped to 23 per hundred thousand (116 deaths).

In 1944 we were again desirous of obtaining tangible evidence of the results of the work. Therefore we tested the children in the same grade schools as in 1926 and 1936, with the result that among the 6,668 so tested the incidence of infection ranged from 2.1 per cent at 6 years to 12.5 per cent at 14 years (chart 1), with an average of 7.7 (chart 2). Thus, only one in each thirteen children was found to be a potential case of clinical tuberculosis in adult life. While this is a worth while accomplishment, we still have a significant tuberculosis problem among school children. Indeed, there will be a problem as long as a single child reacts to tuberculin; therefore the control measures must be increased and further intensified.

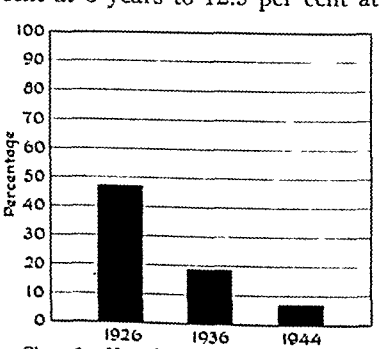

Chart 2.—Note decrease in primary tuberculosis (tuberculous infection) among children in the same grade schools between 1926 and 1944.

As the work progressed we deviated in several respects from the conventional method of administration of the tuberculin test. For example, in 1926 and 1936 the platinum needles were flamed after each test was administered. In 1944 the needles were not flamed

except when they came in contact with something other than the cleansed skin of the children. In no case was skin infection observed. This method doubles one's capacity for work, as it requires as long to flame the needle as it does to administer the tuberculin.

In 1926 and 1936 we used 0.1 mg. of tuberculin for the initial test. Those who did not react were given 1.0 mg. However, we are convinced that in areas where the incidence of tuberculous infection is low a milligram of tuberculin is a safe initial dose. We have employed this dosage in other work for a number of years. Therefore in 1944 the children in this study received a single test dose, consisting of 1.0 mg. No child reacted to a 4 plus degree, and we saw no more 3 plus reactions than had previously occurred when the 0.1 mg. dose was employed. The omission of the conventional first dose reduced the time consumption by about one half, as the second dose would have been necessary in approximately 95 per cent of our children.

All testing was done by one physician in order to insure uniformity of administration. From four hundred to five hundred tests were administered per hour. The same physician made the interpretation at the end of seventy-two hours, a procedure strongly recommended by the Committee on Tuberculosis of the Minnesota State Medical Association. This is far better than the usual forty-eight hour interval, because such conditions as mild hyperemia resulting from trauma have usually disappeared within seventy-two hours, whereas characteristic tuberculin reactions (induration or edema of 5 mm. or more in diameter) are still present and can be read as well even at ninety-six hours.

As tuberculosis is a contagious disease, obviously every child who reacts to tuberculin has been in contact directly or indirectly with a person or an animal that is disseminating tubercle bacilli. The source of the infection is often unknown to the reactor because many persons with clinical tuberculosis are contagious long before they are aware of the presence of their disease. Even among persons ill from tuberculosis rarely do more than 50 per cent know of the source of their original infection. Among the 512 children in our 1944 study who reacted to tuberculin the families of 385 had no knowledge of there having been contact with contagious cases of tuberculosis. Three families refused information, and eleven were not available for history of exposure. Twenty-seven had been exposed to tuberculous mothers or fathers, and 72 to other persons with contagious disease. For the remaining 14 children no direct contact was known, although relatives, such as grandparents, aunts and uncles, had suffered from clinical tuberculosis. Obviously, if we had examined only the children with known history of contact the majority of those with primary tuberculosis would not have been discovered.

Seeking the source of infection among school children who react to tuberculin is a potent case finding method wherever the incidence of tuberculosis is low. We have practiced this procedure a great deal and have found it fruitful; therefore it was strongly recommended that the adult members of the families of the 385 children who had no knowledge of contact with contagious cases be examined, as well as other close adult associates. This phase of the work has only begun, but its effectiveness is illustrated by the following: A girl in the third grade reacted to tuberculin but the x-ray films of her chest were clear. There was no known exposure. Examination of the parents revealed moderately advanced bilateral pulmonary tuberculosis in the father. His throat clearings contained numerous tubercle bacilli. At this time he was a university instructor with no knowledge of the presence of tuberculosis.

Chronic reinfection type of pulmonary tuberculosis is a disease of adulthood, both among human beings and among domestic animals. For example, Chadwick [5] reported that in the examination of large numbers of grade school children he found only 1 child in each 3,300 examined to have the reinfection type of pulmonary tuberculosis. In our studies at Lymanhurst we found only 1 such child in each 2,016 examined.[6] Many years ago, because of the rarity of this condition we discontinued making periodic x-ray films of the chests of the tuberculin reactors until they attained early adulthood. However, all children when first found to react to tuberculin should have one x-ray film inspection of the chest, as this may lead to detection of nontuberculous disease of the lungs and pleura as well as abnormalities of the cardiac outline. For this reason we recommended such inspection of the chests of the reactors. This was done also because among those of 12 years or older there is the possibility of finding an occasional chronic reinfection type of lesion which has attained sufficient size and consistency to cast a shadow visible to the unaided eye. It also provided an opportunity to emphasize that those who are already young adults and all others, as soon as they reach this period, should have annual examination, always including x-ray film inspection of the chest.

The families were advised to consult their private physicians for x-ray films of the reactors. In the event of inability to afford such service they were referred to a chest clinic. Among the 512 reactors there were 5 refusals, and 6 had moved and were not located. Two consulted physicans who advised against use of the x-rays, and 4 had fluoroscopies, as recommended by their physicians. Of the remaining 495 children the films were clear in 421. There was evidence of calcium deposits in 68, pleural adhesions in 4, bronchiectasis in 1 and pneumonia in 1. As was anticipated, no child presented evidence of lesions which might represent the reinfection type of chronic pulmonary tuberculosis. However, each of the 512 reactors is a potential case of this type of disease.

The finding of evidence of calcium deposits by x-ray has no significant meaning. The enthusiasm often manifested concerning evidence of calcium in the parenchyma, hilus or both, including some of our own previous writings, is, in our present opinion, "much ado about nothing." Postmortem findings by pathologists compared with x-ray evidence, both ante mortem and post mortem, even with the lungs removed and inflated, have shown that in only a relatively small number of persons in whom calcium deposits are actually present is there any evidence of its existence by x-ray inspection. Miller [7] found that "calcification of tuberculous first infection in the thorax is demonstrable roentgenographically in only about one fourth of the existing cases." Sweany [8] has shown that only about 20 per cent of the primary tuberculous infections in the chest

8. Sweany, H. C.: Studies on the Pathogenesis of Primary Tuberculous Infection: I. The Regressive Lesions, Am. Rev. Tuberc. **27**: 559, 1933.

are detected by x-ray. Therefore, if one was to require x-ray evidence of calcification before making a diagnosis of primary tuberculosis, even if all calcification were due to this disease, one would miss 75 to 80 per cent of the cases.

The presence of x-ray evidence of calcium does not necessarily denote a healed lesion. Calcium is deposited in dead material, and at the same time disease may be present in adjacent living tissue which is not demonstrable by x-ray. The deposition of calcium does not indicate specificity for any disease; indeed, there are many nontuberculous conditions in which it is deposited. As many as 5 to 25 per cent of lesions which by x-ray were thought to represent primary tuberculous lesions have been found at postmortem to be nontuberculous. Therefore, if instead of testing the entire 6,668 children with tuberculin in 1944 we had just made x-ray film inspections of their chests, in only 68 of the 495 with primary tuberculosis would there have been sufficient evidence to suspect its presence. Thus, the remaining 427 children and their families would have been given a false sense of security with reference to the future potentialities pertaining to clinical tuberculosis, as they would have been told that they were free from tuberculosis. By the method employed we detected 512 actual cases of tuberculosis (we do not use "tuberculosis" synonymously with consumption) in some phase of its development. It is certain that some of the lesions already present, together with the accompanying allergy, will be responsible for the development of clinical tuberculosis at a later time. In what percentage this will occur we do not know, but our experience[9] in dealing with tuberculosis among children and adults for approximately twenty-five years, together with Bogen's careful analysis of the toll of tuberculous infection, has taught us that enough of the reactors develop clinical tuberculosis in later life so that it is extremely important to examine every adult periodically who reacts to tuberculin.

In 1939 Stewart[10] determined the infection attack rate to be approximately 1 per cent annually among Minneapolis children. Apparently this has decreased considerably; in fact, among the children of 6 years tested in 1944 the rate was one third of 1 per cent. The local health department,[11] the tuberculosis association and the medical society tested 7,518 junior and senior high school students in 1942 and 1943, and 941 (12.5 per cent) reacted.

The opposite extreme has been reported from Cincinnati,[12] where 3,622 high school students voluntarily had x-ray film inspections of their chests, and "from the x-ray findings 82.5 per cent showed primary phase tuberculosis: 70.1 grade 1, 10.2 grade 2 and 2.26 grade 3." This report, if the interpretations are correct, indicates an extremely serious situation among the children of Cincinnati. Indeed, the figures would indicate that this city is in a predicament no less serious than that of Vienna reported by Pirquet[13] in 1907. However, the situation may not be as bad as it appears, since the diagnoses were made entirely from x-ray shadows, which are never specific. Of all the phases of an examination there are only two which are specific —the tuberculin reaction and recovery of tubercle bacilli. Without at least one, diagnosis of tuberculosis in any phase is never justified.

Among 8,993 Minneapolis high school students who had 35 by 35 millimeter photofluorograms of the chest, approximately 1 in 1,500 had shadows which were thought to be due to the reinfection type of pulmonary tuberculosis. Among 3,622 Cincinnati high school students who had 4 by 10 inch photofluorograms, only 2 had such shadows. Concerning both of these studies the following statement was made: "It would seem that the high school is not the place to find tuberculosis." Evidently the word "tuberculosis" is used synonymously with consumption or gross lesions and if one is satisfied to postpone finding tuberculosis until it has reached such proportions the statement is correct. This seems paradoxical, however, at a time when so much is being said about finding the disease early and when the tuberculin test reveals its presence within three to seven weeks after focalization of bacilli. In reality, among 7,518 Minneapolis students tested 941 had tuberculosis in the strict sense of the word.

The invention of the stethoscope and the discovery of the tubercle bacillus were hailed with much enthusiasm, but both proved to be helpful in diagnosis usually after the disease is extensive. The x-ray film inspection of the chest is now in the limelight because it often detects shadows of lesions before they cause symptoms. However, enthusiasm for the x-ray is beginning to wane with the stark realization that it too is a method for locating areas of gross disease and therefore is not the earliest possible diagnostic procedure. However, it is the best we have to detect the location of reinfection type of lesions after they become macroscopic and are located in parts of the lung which are visualized on the film.

Among adult tuberculin reactors are those destined to develop chronic reinfection type lesions, and the most important step is to find these lesions while they are early and before they have caused illness or have become contagious. For almost a quarter of a century in the Tuberculosis Service of the Minneapolis Division of Health (formerly Lymanhurst) we have studied the various methods of detecting early lesions.[9] At first stereoscopic x-ray films were made of the chests of all persons examined, regardless of reaction to tuberculin or symptoms. These inspections were made annually for sizable groups of individuals. In some whose chests were originally clear on x-ray inspection there later appeared one or more areas with changes so slight that one could not determine whether lesions were actually present. Frequent periodic inspections in some of these cases, however, left no question as to the presence of lesions which slowly produced larger and larger shadows, and ultimately by other methods the majority of them were found to be tuberculous. Not all early demonstrable lesions are minimal. Occasionally the person whose film is clear may within three to six months have evidence of advanced disease.

On analysis we discovered that all persons who developed chronic tuberculous lesions under our eyes came from the group of tuberculin reactors. Moreover, these lesions usually did not become visible except in adulthood. Therefore we discontinued making films of the chests of nonreactors to tuberculin in all age periods because it seemed futile to be looking for something that could not possibly exist by reason of absence of tubercle bacilli. Of all the methods used we came

to the conclusion that the only one which is scientific, accurate and wholly satisfactory for discovering the early chronic tuberculous lesion is that which makes annual x-ray inspections of the chests of adult tuberculin reactors, with complete examination of those with lesions which cast shadows.

The medical profession is seriously in need of a criterion by which one can determine whether a given tuberculin reactor will ever develop clinical tuberculosis. However, its realization seems most remote, since the evolution of clinical disease depends on several factors: 1. An infection that is definitely present today may completely disappear over a period of months or years; that is, all the tubercle bacilli in the lesions die. 2. Reinfections from exogenous sources may or may not occur. 3. The walls which nature establishes around the tubercle bacilli in the lesions of primary complexes may serve as permanent prisons for the organisms. On the other hand, they may be resorbed or trauma may rupture them so that the tubercle bacilli are liberated, to find lodgment on allergic tissue (endogenous reinfection). Since such a criterion probably is not possible, it would be helpful if one was available to determine when an individual begins to develop the reinfection type of tuberculosis; that is, when the disease is in the preclinical stage and before it has attained such gross proportion as to cast x-ray shadows. Caulfeild,[14] Ogden[15] and others believe such a diagnostic agent is now available in the Caulfeild inhibitive reaction and the tuberculin complement fixation test.

In most parts of the world at present the children constitute the only group over which one can exercise complete tuberculosis control. The child is born free from tubercle bacilli, and if his environment is adequately guarded his body will remain uncontaminated with these organisms. This necessitates complete examination of all who are to be his adult associates to find (1) those who already have clinical tuberculosis and (2) those who react to tuberculin and are potential cases of such disease. Those who on first or subsequent examination are found to have clinical tuberculosis must be kept from the child's environment unless it can be proved continuously that their disease is not contagious. The child himself should be tested periodically to make sure that no unsuspected contagious case among transients and the like has come into his environment and infected him. This procedure should not be limited to childhood but should be continued when adulthood is attained. This is not a theoretical consideration of idealists. It is actually in practice with a high degree of success and must be the ultimate goal in every home and community.

Science and War.—But science is our consolation and refuge; today every nation respects it: in the midst of the tumult of war the descendants of Archimedes among us have nothing to fear from an enlightened soldiery, to whom their names and their work are known and who are happy to become for the moment their disciples. Perhaps it is actually in the most terrible times that, taking refuge in the cloisters of meditation, shunning in the exaltation of their spirit the horrors that surround them, they sometimes attain the most fortunate conclusions, the most fruitful discoveries We shall see that the list of accomplishments for this year yields nothing to those of our most peaceful years.—Olmsted, J. M. D.: François Magendie, New York, Schuman's, 1944.

PENICILLIN AND SULFONAMIDES IN THE THERAPY OF ACTINOMYCOSIS

REPORT OF SIXTEEN ADDITIONAL CASES AND IN VITRO TESTS OF SUSCEPTIBILITY OF ACTINOMYCES TO PENICILLIN AND SULFADIAZINE

LEONARD DOBSON, M.D.
AND
WINDSOR C. CUTTING, M.D.
SAN FRANCISCO

In 1941 we [1] reported 3 cases of actinomycosis successfully treated with sulfanilamide. Since then we have collected 16 additional cases treated in the Stanford medical, pediatric and surgical services at Stanford-Lane Hospitals, at the San Francisco Hospital and as private patients. These cases of actinomycosis include 3 of the pulmonary, 2 of the abdominal and 11 of the cervicofacial types.

In the last three years a number of articles have reported the use of sulfonamides in the treatment of actinomycosis.[2] The opinions expressed in general have been that the sulfonamides are of great value. Not only the cervicofacial types but also extensive abdominal and pulmonary types have been cured, or at least arrested, for long periods of time after the use of sulfonamides.

Penicillin has been used for too short a time to draw final conclusions as to its efficacy in treating actinomycosis. Herrell, Nichols and Heilman [3] reported the use of penicillin in 12 cases of actimomycosis. There was failure in 2 cases, a satisfactory result in 2 and a doubtful result in 8. These authors plan to give a detailed report at a later date. Other reports on the use of penicillin in the treatment of actinomycosis [4] deal with small numbers of cases, most of which have been followed for short periods of time. The general impression gained is that penicillin is an effective agent in treating actinomycosis. Several failures, however, have been reported.

Our purpose in the present paper is to compare the effectiveness of penicillin and the sulfonamides in the

From the Departments of Surgery and of Pharmacology and Therapeutics, Stanford University School of Medicine.

Part of the penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council

treatment of actinomycosis. Like Herrell and his associates, we feel that no final conclusions should be drawn with less than an eighteen month follow-up period. However, the sulfonamides and penicillin proved so effectual in most of our cases that we are reporting them to encourage others to use these drugs in order that a larger series of cases may be accumulated from which definite conclusions may be drawn. In addition to the study of the 16 cases of actinomycosis, various concentrations of penicillin and sulfadiazine were observed for their effects on different strains of Actinomyces in vitro.

REPORT OF CASES

Table 1 summarizes the case reports, listing the type of case, the drug or drugs used and the end result. Three cases were treated with penicillin alone, 3 with penicillin and sulfadiazine, 6 with sulfadiazine, 1 with sulfadiazine and sulfathiazole, 1 with sulfathiazole and 2 with sulfanilamide.

CASE 1.—G. R. F., a man aged 37, noticed a swelling on the left side of his neck three months before entry. This was compressed and then lanced and Actinomyces organisms were demonstrated in the pus. He was then treated by roentgen irradiation, ten doses of 200 roentgens, after which the swelling became nodular. Potassium iodide also was given for two weeks.

On admission to the penicillin ward in Stanford Hospital on March 15, 1944, examination was not remarkable except for an indurated swelling at the angle of the left jaw, from which yellow pus could be expressed in several places (*fig. 1*).

During the first six days after hospitalization he was treated with penicillin by continuous intravenous drip, the total dosage being 1,030,000 units. During the next thirty-two days he was given 120,000 units daily by three hourly intramuscular injections, so that the total by all routes was 4,655,000 units. He improved steadily, and only a few minimal nodules, without secretion, remained when he was dismissed. During the following month a mild discharge occurred on two occasions from the flattened nodules, but, in general, these decreased in size. Eight months after leaving the hospital he remained entirely well with no induration or swelling of the originally involved area (*fig. 2*).

This patient had an extensive cervicofacial type of actinomycosis. During a three months period the infection continued to spread in spite of iodide and roentgen therapy. A rapid and apparently complete healing occurred after the administration of 4,655,000 units of penicillin.

CASE 2.—M. M., a man aged 38, had had swellings over the left cheek and beneath the left ear for five months when he was first seen at Stanford Hospital. Occasionally the swellings broke down and discharged pus. He had had several teeth extracted and was given a one week course of sulfonamide therapy, all without any lasting benefit.

On admission to the penicillin ward on May 22, 1944 he was afebrile, with a crusted lesion on the left cheek near the ear and a tender swelling 6 cm. in diameter over the left malar bone. There was pus draining into the left auditory canal through a fistula in the upper wall. Examination was not otherwise remarkable except for expression of pus from the lesion, which contained the organisms of actinomycosis.

He was treated by intramuscular injections of penicillin at three hour intervals. During the first three days the daily dosage was 200,000 units, the next five days it was 120,000 units and the remaining nine days of treatment it was 40,000 units. The total dose during the seventeen days was 1,560,000 units. Healing was remarkably rapid, and no evidence of the lesion was apparent at the conclusion of treatment.

Rapid healing occurred in this case of cervicofacial actinomycosis of five months' duration by the administration of 1,560,000 units of penicillin over a seventeen day period.

CASE 3.—J. G., a man aged 56, a shipyard worker, entered the medical service of Lane Hospital on Aug. 21, 1944 complaining of fever and a severe cough. Four months previously he had started to lose weight. A chronic cough became much worse and he was hospitalized as a private patient and was given sulfadiazine for one month and penicillin for eight days. He improved and returned home feeling better. A week later, however, he developed a tender swelling in the right flank, and his local physician drained an abscess in the right lumbar region.

On entry he had a fever of 39.5 C. (103.1 F.) and there were numerous rales over both sides of his chest. X-ray examination showed scattered densities in both lung fields with encapsulated fluid in the right lower chest. The right psoas muscle shadow was obscured and the entire retroperitoneal area appeared cloudy. Thin yellow fluid drained from the right flank incision. On September 1 typical sulfur granules of actinomycosis were identified in the drainage. All cultures were heavily overgrown with Staphylococcus aureus, but the fungi were not isolated.

TABLE 1.—*Summary of Case Reports*

Case	Type	End Results
Penicillin		
1. Mr. G. R. F.	Cervicofacial	Cured
2. Mr. M. M.	Cervicofacial	Arrested
3. Mr. J. G.	Pulmonary	Arrested
Penicillin and Sulfadiazine		
4. Mr. A. D.	Cervicofacial	Arrested (alternate course)
5. Mr. J. McB.	Cervicofacial	Arrested (combined)
6. Mr. G. W.	Pulmonary	Arrested (alternate courses)
Sulfadiazine		
7. Mr D. P.	Cervicofacial	Cured
8. Mr. A. L.	Cervicofacial	Cured
9. Mrs. C. R.	Cervicofacial	Cured
10. Mrs. J. P.	Cervicofacial	Arrested
11. Mrs. I. B.	Abdominal	Arrested, 14 months
12. Mr. F. B.	Pulmonary	(Short course) (died)
Sulfadiazine and Sulfathiazole		
13. Miss M. M.	Cervicofacial	Cured
Sulfathiazole		
14. Mrs. M. W.	Abdominal	(Died)
Sulfanilamide		
15. Miss H. M.	Cervicofacial	Cured
16. Mr. D. M.	Cervicofacial	Cured

Cured: Followed for 6 months to 4 years after all therapy was stopped.
Arrested: No evidence of active disease, but there was too short a follow-up period to claim a cure.

He was started on penicillin on September 4, receiving 200,000 units daily intramuscularly. On September 21 the daily dose was reduced to 120,000 units. By October 11 he had received 4,300,000 units. The sinus was healed by September 26. The temperature became normal and remained so after the first week of treatment. On September 28 roentgenograms showed improvement in both lungs. On October 9 both lungs were practically clear on physical examination.

He was dismissed on October 13, and examinations in the outpatient clinic have shown that he was gaining weight and was without cough or fever, and that the chest remained clear.

Penicillin produced a prompt and decided improvement in this patient's pulmonary and retroperitoneal actinomycosis. He cannot be considered cured and will be closely followed. This case also illustrates the usual difficulty in establishing the diagnosis of actinomycosis until sulfur granules are found in the pus.

CASE 4.—A. D., a man aged 46, Spanish, a cleaning establishment operator, entered the San Francisco Hospital on April 9, 1944 complaining of a painful swelling on the right side of his neck. Three weeks previously he had had an upper respiratory infection complicated by a sore throat. An abscess formed, which broke spontaneously into his throat. The day before

admission a painful swelling developed in the upper right side of his neck. Examination showed a hard swelling of the right neck from the angle of the jaw to 4 cm. above the clavicle. The right tonsil was pushed forward and the uvula was displaced to the left. He was considered to have a peritonsillar abscess with cellulitis of the neck. He was treated with sulfadiazine, 1 Gm. every four hours. The fever subsided but the swelling persisted. On the twelfth day an incision was made below his right jaw and only indurated tissue encountered. Microscopic examination did not show Actinomyces. On May 5 dental roentgenograms showed extensive bony destruction around the roots of the right lower third molar. On May 9 the lower three molars were extracted. On May 25 a fluctuant abscess at the right angle of the jaw yielded thick yellow pus containing granules typical of Actinomyces bovis. These were identified on repeated examinations, although the organisms failed to grow on culture. On May 26 the sulfadiazine was stopped after administration of a total of 294 Gm. and the patient was started on penicillin 15,000 units intramuscularly every three hours (120,000 units daily). Within two days after starting the penicillin his condition showed much improvement. The swelling rapidly subsided and the drainage decreased until by June 22 it had ceased. He was discharged on June 28 with only a slight soft swelling below the angle of his jaw. He received a total of 4 million units of penicillin.

Fig. 1 (case 1).—Extent of involvement before treatment with penicillin.

This case illustrates the difficulties of establishing an early diagnosis of actinomycosis, even when it is suspected and repeated examinations are made to find the organism. The patient improved on sulfadiazine but the infection became stationary. The infection rapidly subsided with the administration of 4,000,000 units of penicillin. The bony involvement made necessary the intensive and more protracted course of therapy.

CASE 5.—J. McB., a man aged 41, a cook, developed a painless swelling in the right temple on Dec. 15, 1943. On December 26 he had two lower right molar teeth extracted, but the swelling continued to increase. He was brought to Stanford Hospital on Jan. 7, 1944, at which time he had a large fluctuant swelling in the right temple and an indurated swelling of the right side of his face extending down to the angle of the jaw. The abscess was drained of 50 cc. of thick yellow-gray pus. Actinomyces organisms were obtained on smear and subsequently identified on culture. Treatment with 1 Gm. of sulfadiazine every four hours led to rapid improvement. He was dismissed on January 12 and kept on full dosage of sulfadiazine at home. By March 3 the incisions had healed and the swelling had disappeared. The sulfadiazine was discontinued on March 3, but three weeks later the swelling in the right temple recurred and he was again given full dosage of sulfadiazine. On April 3 roentgen therapy and potassium iodide were started. In spite of the combined therapy of sulfadiazine, x-rays and iodide, the firm swelling in the right temple persisted and he began to have more difficulty in opening his mouth. A roentgenogram of the facial bones showed an area of bony destruction in the maxillary process of the right malar bone and an obscure right maxillary sinus.

On readmission May 19 to the penicillin ward he was started on 15,000 units of penicillin intramuscularly every three hours, a total of 120,000 units daily. By June 12 a total of 3,000,000 units had been administered. The swelling diminished and became softer and he could open his jaw better. He left the hospital on June 13, but by June 21 the swelling had started to increase again. Roentgenograms, however, showed healing of the malar bone. He was readmitted to the penicillin ward and started on June 29 again with 120,000 units of penicillin daily, continuing to July 23 to a total of another 3,000,000 units. As the penicillin therapy produced no definite improvement, treatment with sulfadiazine, 1 Gm. every four hours, was started on July 15. Under the combined therapy of penicillin and sulfadiazine the patient slowly improved, but there was still some swelling in the right temple on dismissal from the hospital on July 24. He was continued on 1 Gm. of sulfadiazine every four hours for one month and then given 1 Gm. every six hours for four months. The swelling disappeared and he has been free from symptoms for the past three months and working the past four months.

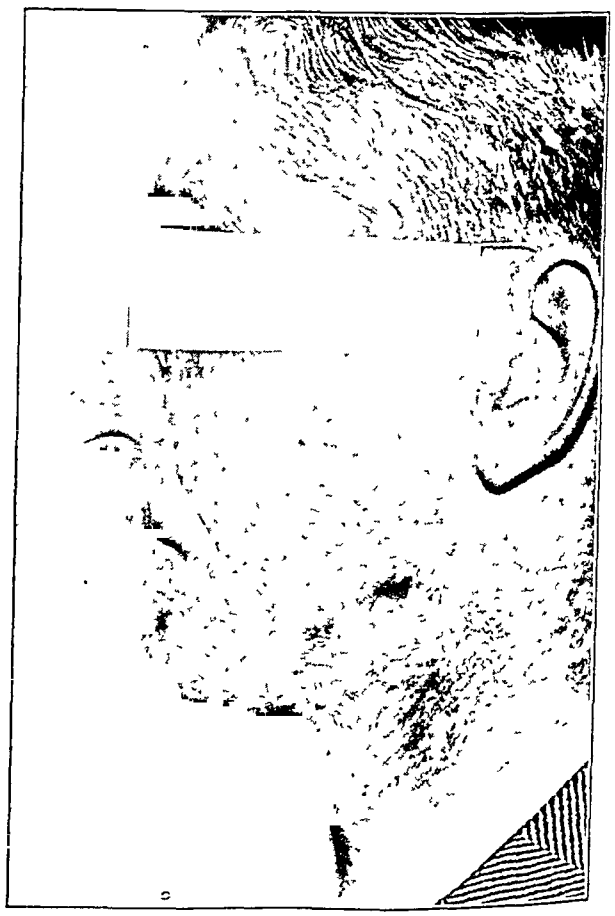

Fig. 2 (case 1).—Seven months after treatment with penicillin.

As in case 4, this illustrates the greater difficulty in obtaining a cure when there is extensive bony involvement. This proved the most difficult to control of the 11 cases of cervicofacial actinomycosis in this series. The patient was treated with sulfadiazine for seven months and received 6,000,000 units of penicillin in addition to surgical drainage, potassium iodide and roentgen therapy. A longer period of observation is necessary before he can be considered cured.

Fig. 3 (case 6).—Appearance of chest on July 31, 1943, showing the massive pleural empyema

CASE 6.—G. W., a man aged 39, a railroad switchman, entered the San Francisco Hospital on July 29, 1943 complaining of pain in the left side of his chest. He was an alcoholic addict For fourteen months he had had a chronic cough which produced a cupful of sputum daily. Three weeks prior to entry he suddenly developed a pleuritic pain in the left side of the chest, which gradually became a steady, dull ache under the left scapula and along the left costal border and his dyspnea increased.

A massive pleural effusion (fig. 3) was found on admission On July 31 750 cc. of purulent fluid was withdrawn from his left chest. Culture showed Actinomyces, but the exact strain was never identified. On August 6 an Eloesser flap was made in the left chest and 5,000 cc. of pus evacuated (figure 4 gives the appearance of the chest after drainage). Sulfadiazine was started on August 19, 1 Gm. every six hours. Lugol's solution was given also and the dosage gradually increased until he was receiving 33 drops three times daily by September 2. He also received ten roentgen radiation treatments of 100 roentgen units each to the left chest.

He improved rapidly and gained weight. The drainage from the left chest rapidly diminished. A roentgenogram of the chest on November 24 showed definite clearing of the density in the left lung field. He was discharged from the hospital on Nov 26, 1943.

Shortly after leaving the hospital he developed a severe upper respiratory infection, with a cough and an increase in drainage from the chest flap. He was readmitted on December 28, and on Feb. 9, 1944 again started on sulfadiazine, 1 Gm. five times daily to July 20 There was a slow general improvement but his sputum continued to contain Actinomyces granules. On August 11 he was started on a daily dose of 100,000 units of penicillin intramuscularly, which was decreased to 50,000 units daily on September 1. The penicillin was continued to October 28, a total of 5,000,000 units being given over the ten week period. At the time of his dismissal he was in excellent condition, without evidence of any pulmonary activity (figure 5 shows one of the latest chest films).

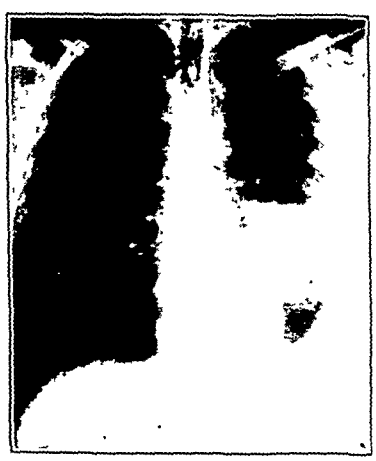

Fig. 4 (case 6).—Chest on Sept 14, 1943 showing extent of involvement of left lung after pleural drainage.

This patient had a chronic lung infection for fourteen months before he was brought to the hospital with a massive empyema. Organisms of the Actinomyces group were cultured from the empyema pus and repeatedly seen in granules in the sputum, but the exact species could not be identified. Surgical drainage and a nine week course of sulfadiazine produced definite improvement. A month after he left the hospital his cough and the drainage increased and he was readmitted. He was given sulfadiazine therapy for five months more and then 5 million units of penicillin. His case is considered arrested and he will be followed for an additional eighteen months before he can be considered cured.

CASE 7.—D. P.,[5] a man aged 30, a shipyard worker, developed a mass in the left submaxillary region in July 1943, six weeks after the extraction of a left lower molar tooth. During the next five weeks the mass increased in size, became fluctuant and finally ruptured through multiple sinuses The pus contained Actinomyces bovis.

The fluctuant area was drained surgically and a 50 per cent suspension of sulfadiazine in isotonic solution of sodium chloride instilled three times a day. Sulfadiazine also was administered intravenously, and then orally, to maintain a concentration of 12 to 15 mg. per hundred cubic centimeters in the blood. Iodide and thymol also were administered. Within two weeks the lesions had literally disappeared. One week later the urine became grossly bloody and the sulfadiazine was stopped, but the iodide and thymol were continued and the lesion was given 1,200 roentgens in divided doses.

Fig. 5 (case 6).—Chest on May 1, 1944, showing pronounced clearing of the left lung base.

In spite of this adjunct therapy, the mass and sinuses recurred a month after sulfadiazine was stopped, involving a more extensive region than originally. Sulfadiazine was resumed intravenously and then orally in doses adequate to produce a blood concentration of 15 to 25 mg. per hundred cubic centimeters. This required 4 Gm. every four to six hours. Local treatment was carried out, as when first seen. Fluids were given in large amounts and 15 Gm. of sodium bicarbonate was administered, in divided doses, each day. No toxic symptoms developed despite the high dosage of sulfadiazine, and the lesions again disappeared rapidly. Within one month the lesions and incisions had been replaced with firm scar tissue, but the therapy with sulfadiazine was continued for three more months. By this time the scars and deep seated induration had become quite soft and pliable. At present the patient is at work, apparently completely cured

It is obvious that treatment on the first occasion (three weeks) was inadequate and that the longer period (four months) was necessary to achieve complete cure. The recurrence and progression of the disease under iodide, thymol and roentgen irradiation are indicative of the low efficacy of these agents. The dose of sulfadiazine 4 Gm. every four to six hours is phenomenal but shows that these high doses and correspondingly high blood concentrations may be safe if the fluid intake is large and the urine is maintained on the alkaline side of neutrality.

5. The patient was seen through the courtesy of Dr Irving Wiesen *teld of the Permanente Hospital, Oakland, Calif.*

CASE 8.—A. L., a man aged 42, a farmer and welder, was admitted to the San Francisco Hospital on April 1, 1944 for treatment of an abscess on the right side of his jaw. Two weeks previously he had first noticed that he could not open his mouth widely, and a small, painless swelling had appeared at the right angle of the mandible. The swelling increased in size and became painful. Within a week an abscess formed, which was drained at the Stanford Clinic. The pus contained typical granules of Actinomyces bovis.

Examination on admission showed a swelling of the right jaw extending from the zygoma to about an inch below the body of the mandible. The swelling was firm and not tender except over the angle of the jaw. The incision along the inferior surface of the mandible was draining thick creamy pus. A roentgenogram of the mandible showed a large abscess around the root of the right second molar. On the third day the patient's temperature rose to 104.4 F. Hot compresses were started and continued for three weeks. Treatment with sulfadiazine 1 Gm. every four hours was continued for nineteen days to the time of his discharge from the hospital. On April 15 the affected molar was extracted. Cultures from the tooth socket isolated organisms of the Actinomyces group, hemolytic Staphylococcus albus, and anaerobic, gas producing bacilli.

He improved rapidly, the swelling subsided and the drainage decreased. A 2 cm. area of induration at the angle of the jaw was still present when he was dismissed to outpatient care. Seven months later he still showed no evidence of recurrence.

Adequate surgical drainage and nineteen days of sulfadiazine therapy produced a rapid cure. A diagnosis made early in the disease was no doubt an important factor in obtaining a cure.

CASE 9.—Mrs. C. R.,[6] aged 58, a housewife, developed a swelling below the left jaw in the middle of November 1943. A week later the lower left canine tooth was extracted, but the swelling increased and spread down into the left submaxillary region. A week later a small submaxillary abscess drained and typical sulfur granules were found in the pus and Actinomyces bovis was identified on culture. The patient was started on sulfadiazine therapy 1 Gm. every four hours, and this was continued for two weeks. At the end of that time the incision had healed and at the end of one month all induration was gone. One year later there is no evidence of a recurrence.

A prompt complete healing of the cervicofacial actinomycosis occurred after drainage and two weeks of sulfadiazine therapy. There has been no recurrence in one year.

CASE 10.—Mrs. J. P., aged 25, developed a swelling along the border of the mandible seven weeks after the removal of a carious third lower molar tooth. Two weeks later (Nov. 19, 1943) the lesion was opened surgically and the organisms of actinomycosis were demonstrated in the pus. No osteomyelitis was demonstrated by roentgenograms.

Treatment was intermittent during the first month and consisted of about fourteen days of active therapy with sulfathiazole or sulfadiazine in doses of about 1 Gm. every four hours. Iodide was also taken irregularly during this time. After this she had continuous treatment with sulfadiazine 1 Gm. every four to six hours, together with adequate fluids and sodium bicarbonate to keep the urine dilute and alkaline. She was also given Strong Solution of Iodine, U. S. P., 10 to 20 drops three times a day. No x-ray therapy was administered. At the end of two months she stopped treatment entirely because she felt perfectly well. Two months later she reported by letter that she considered herself well and that the army medical officers where her husband was stationed considered her cured.

Drainage and sulfadiazine produced a rapid improvement and possible cure in this case. Inadequate follow-up prevents the case being listed as a cure.

6. Seen through the courtesy of Dr. Robert S. Irvine, Department of Ophthalmology, Stanford Medical School

CASE 11.—Mrs. I. B., aged 41, a clerk, entered the surgical ward of Lane Hospital on Aug. 20, 1943 for treatment of a recurrent abscess on the right lower abdomen. In 1936 exploration for a ruptured appendix had been done. For the following six years she repeatedly developed abscesses in the right lower abdomen which were either drained by incision or ruptured spontaneously. Five days prior to admission the painful swelling recurred in the right lower quadrant. Examination showed a 10 cm. tender area of induration at McBurney's point.

On the day of admission a McBurney incision was made and an abscess drained, the pus containing typical sulfur granules. Sulfadiazine therapy was started, 1 Gm. every four hours. The patient was dismissed on the seventh day and continued on sulfadiazine at home, receiving a total of 125 Gm. of sulfadiazine in a three week period. The abdominal wound healed in three weeks. Examination on Dec. 6, 1944, fourteen months after drainage of the abscess, showed the abdomen to be soft and nontender.

Although more than fourteen months have passed since the last recurrence of the abdominal actinomycosis, the patient must be followed for another year before being pronounced cured. Without medication she has gone as long as ten months previously between recurrences. The relatively short course of sulfadiazine has arrested the infection for a long period and perhaps cured it.

CASE 12.—F. B.,[7] a man aged 63, a retired banker with severe diabetes, developed a productive cough in February 1943. He then began to have night sweats and soon lost weight and strength. From the sputum and from subcutaneous nodules a fungus was isolated, first called Streptothrix and later identified as Nocardia (Actinomyces) asteroides.

On four occasions he was given a week's course of sulfadiazine (1 Gm. every four hours), and during each of these periods he improved and his fever remitted. This therapy was not persisted in, however, and he slowly became weaker. He was transferred from the care of his private physician to the Stanford Medical Service on May 8, 1943.

Examination on admission showed that he was extremely ill and in great respiratory distress. There were multiple, firm, fluctuant nodules in the skin and subcutaneous tissues of the arm, chest and abdomen. Chest examination showed extensive bilateral pulmonary involvement. He failed to respond to sulfadiazine therapy and died on May 11.

Autopsy revealed numerous subcutaneous abscesses containing the fungus. Similar abscesses were found in the lungs, heart, kidneys, thyroid and psoas muscles.

In comparison with the successfully treated cases, the brief periods of treatment with sulfadiazine in this case seem highly inadequate. The immediate benefit from each course of sulfadiazine probably indicates that more prolonged therapy might have been curative.

CASE 13.—M. M., an Indian girl aged 9 years, was admitted to the pediatric service of Stanford-Lane Hospitals on Feb. 7, 1942 for treatment of a swelling of the right side of the face. The swelling was first noticed two months previously over the right angle of the jaw. On entry, physical examination revealed a swelling at the angle of the right mandible with a small superficial abscess over it and some purulent drainage at the base of the second right molar. Roentgenograms on Feb. 7, 1942 showed bony destruction and new bone formation involving about half of the right mandible. On February 9 pus from a sinus below the angle of the jaw contained sulfur granules typical of Actinomyces bovis. Sulfadiazine therapy was started, 4.1 Gm. daily for seventeen days and slightly smaller doses for five more days being given. She rapidly improved. The sinus was healed within two weeks and the swelling gradually receded. She was dismissed on March 4 after receiving a total of 84 Gm. of sulfadiazine.

7. To be reported in detail by Drs. James McNaught and William M. M. Kirby, Stanford Medical School

After two weeks at home the swelling of the jaw recurred and she was readmitted to the hospital on April 8, 1942. Although roentgenograms showed continued healing of the mandible, sulfur granules were again present in the pus. She had developed a slight leukopenia while on sulfadiazine, so she was given sulfathiazole, starting with 0.7 Gm. every four hours and then 0.3 Gm. every four hours, from April 15 to May 2, 1942. Again she rapidly improved and was dismissed May 2, 1942. She was followed in the outpatient department and had no evidence of infection when last seen on Nov. 5, 1943, a year and a half later. A roentgenogram on Nov. 5, 1943 showed a normal mandible.

This girl has apparently been cured of a cervicofacial type of actinomycosis in which there was extensive involvement of the mandible. She was much improved by three weeks of sulfadiazine therapy, but an additional three weeks of sulfathiazole was necessary to cure her. This course emphasizes the necessity for a longer period of treatment when there is bony involvement.

CASE 14.—Mrs. M. W., aged 27, a housewife, Chinese, entered the San Francisco Hospital on May 21, 1943 complaining of upper abdominal pain of two days' duration. She died ten days later.

One year prior to entry she began to have attacks of right upper abdominal pain and fever, never accompanied by jaundice. She entered another hospital in December 1942, where a liver abscess was drained posteriorly and Actinomyces was cultured from the pus. A right pleural effusion developed, following the operation, but no organisms were cultured from the fluid. Her weight fell from 101 to 75 pounds (46 to 34 Kg.). She was given sulfathiazole 9 Gm. daily for three weeks followed by 4 Gm. for several more weeks. She was then allowed to return to her home, but within ten days she had a recurrence of fever and right upper abdominal pain.

Examination on admission to the San Francisco Hospital revealed that she was slightly jaundiced. Her temperature was 101 F. A smooth, tender liver extended nearly down to the iliac crest, and the spleen to the level of the umbilicus.

Blood cultures were positive for Actinomyces, type undetermined. Tuberculin and coccidioidin tests were negative. Roentgenograms showed an elevation of the right leaf of the diaphragm and enlargement of the liver and spleen.

Sulfathiazole was started, 1 Gm. every four hours for forty-eight hours. The temperature fluctuated between 101 and 104 F. She became progressively more jaundiced and was comatose before death on May 31. At autopsy the essential findings were multiple abscesses in the liver and between the liver and the abdominal wall. There was a 1 cm. abscess in the submucosa of the stomach on the lesser curvature in the prepyloric area. Numerous sulfur granules were found in the abscesses in the liver and stomach. The lungs showed extensive bronchopneumonia. Dr. Alvin J. Cox of the Stanford department of pathology concluded "There is little doubt that the port of entry for Actinomyces in this case was the stomach, and there is no definite evidence of a previous lesion in this organ. Chronic suppurative lesions were extensive in the liver, accounting for most of the clinical features of the case."

This woman developed actinomycosis of the stomach and liver one year prior to her death. On sulfathiazole therapy she improved rapidly and was considered cured. The infection recurred and was rapidly fatal. Perhaps a longer course of sulfonamide therapy might have cured her. The autopsy findings indicated that the port of entry of Actinomyces was through the stomach.

CASE 15.—A woman aged 47, a school teacher, entered Stanford Hospital on Nov. 18, 1940 complaining of a swollen left jaw. On August 15 she had had two lower left molar teeth extracted. The gums healed, and she had no trouble for six weeks. About November 1 she began to have difficulty in opening her mouth, and a hard, nontender swelling appeared on the left side of her jaw.

Examination on admission showed a lemon sized swelling on the left mandible anterior to the angle. On November 19 the mass was aspirated but no pus was obtained. On November 26 she was started on sulfathiazole, being given 1 Gm. every four hours. On December 1 pus was obtained which contained the typical sulfur granules of actinomycosis. On December 6, after eleven days of sulfathiazole, she developed a generalized rash and a fever, and the drug was discontinued. On December 10 sulfanilamide was started, 1 Gm. every four hours. After two weeks the dose was reduced to 0.5 Gm. every four hours and at the end of one month to 0.5 Gm. four times daily. Under the treatement with sulfanilamide the drainage ceased and the indurated mass gradually diminished in size. She was dismissed seven weeks after starting the sulfanilamide with a 2 cm. area of induration anterior to the angle of the jaw. She was kept on a dosage of 0.5 Gm. of sulfanilamide four times daily for six more months. Now, four years after the onset of her infection, there is no evidence of any recurrence.

This is a four year cure of cervicofacial actinomycosis after use of iodide, x-ray therapy and a long course of sulfanilamide.

CASE 16.—D. M., a man aged 29, a pipefitter's helper, entered the San Francisco Hospital on May 22, 1942 for a swelling of the left side of his face. One month previously a swelling developed over the left mandible below the left parotid. The left eyelids became swollen and he had difficulty in opening his jaw. An abscess, localized in front of the left ear, was drained by his private physician. Actinomyces granules were identified, and he was sent to the San Francisco Hospital. Examination on admission showed a swelling on the left side of his face, involving the preauricular region, the left eyelids and the parotid, submaxillary and upper cervical areas. Roentgenograms showed osteomyelitis involving the left descending ramus of the mandible. On May 29 the incision made originally was enlarged and he was started on sulfanilamide, hot compresses and roentgen irradiation. He was given sulfanilamide 1 Gm. every four hours for four days and then put on sulfathiazole 1 Gm. every four hours for four days. On June 7 he was also given potassium iodide in increasing dosage and his jaws were wired. He received no sulfonamides from June 11 to June 30. On the latter date he was again started on sulfanilamide 1 Gm. every four hours. This was decreased to 0.6 Gm. three times daily, and this small dose was continued to July 19, when it was further reduced to 0.3 Gm. three times daily. He continued to improve. Drainage ceased, the induration diminished and roentgenograms showed healing of the osteomyelitis of the jaw. He was discharged to the outpatient department on Aug. 4, 1942. The jaw was kept wired for two more months. He had returned to work in a shipyard by July 10, 1943 and on Oct. 6, 1943 had no evidence of recurrence.

This case of extensive involvement of actinomycosis of the cervicofacial type was cured by surgical drainage, wiring of the jaws and the administration of iodide and sulfanilamide. We believe that a more intensive course of sulfonamide therapy, preferably sulfadiazine, might have produced a more rapid cure. Also we do not feel that it is necessary to wire the jaws during treatment.

CASE 17 (follow-up note on case 2 in our report in 1941 [1]).—E. Z., a man, now 28 years old, was treated for actinomycosis of the chest wall in 1939. At that time the organisms were demonstrated in smears after the termination of a rather brief course (seventeen days) of sulfanilamide, but he went on to apparent clinical recovery. However, the roentgen appearance of the chest never became entirely normal.

Two years later, in September 1941, he again began to have pain in the right chest. This forced him to reenter the hospital in May 1942. He was febrile and had a moderate secondary anemia. The pleura and chest wall over the right

lower lobe of the lung were involved in an inflammatory process. In spite of repeated attempts, no significant organisms were ever recovered from the sputum or by aspiration of the local lesion.

On the assumption that this was a recurrence of the actinomycosis, he was placed on sulfadiazine 6 Gm. daily. This was reduced in four days to 3 Gm. owing to nausea and crystalluria, and the therapy was continued for seven weeks. The dose was then reduced to 1 Gm. daily and finally discontinued entirely after four more weeks. The total course of treatment was therefore nearly three months. The fever remitted after the first week, and he rapidly gained strength. A few months later he felt well enough to apply for service in the Army but was refused. He then obtained work as a timekeeper, which he has been able to do satisfactorily. However, from time to time he still complains of soreness in the right chest. The most recent roentgenogram, made in April 1943, showed some residual opacities in the right chest.

Conclusions in this case must be circumspect, since it was not proved definitely that the recurrent disease was actinomycosis and there is no certainty that there may not be further recurrences.

IN VITRO TESTS OF SUSCEPTIBILITY OF ACTINOMYCES TO SULFADIAZINE AND PENICILLIN

In an attempt to determine the relative chemotherapeutic potency of sulfadiazine and penicillin against actinomycosis, the direct in vitro effect of these agents was studied. Three strains of Actinomyces [8] were grown for five to seven days in thioglycolate medium to which varying concentrations of the therapeutic agent were added, as shown in table 2. The results obtained with penicillin were somewhat more encouraging than those recently reported by Keeney and his co-workers.[9]

It is apparent that the different strains of Actinomyces vary considerably in their susceptibility to sulfadiazine and penicillin (table 2). If 10 mg. per hundred cubic centimeters in the blood is considered an average good therapeutic level for sulfadiazine, and 0.5 unit per cubic centimeter a high therapeutic level for penicillin, it is clear that sulfadiazine is more potent. With three times this content of penicillin, a level which is seldom maintained under present clinical conditions, penicillin may surpass sulfadiazine in efficacy. In no case does the combination of the two drugs significantly exceed the effect of the separate drugs, especially sulfadiazine, and in some trials the combination appeared to be less effective than sulfadiazine alone.

The inhibitory effect of either drug was usually apparent after one day of incubation, and in certain trials penicillin appeared to be slightly more effective during the first two or three days than at the end of the experiment. This may be due partly to destruction of penicillin in the culture tubes.

The general conclusions may be drawn that, unless exceptionally high concentrations of penicillin are used, this drug appears to be slightly inferior to sulfadiazine against various strains of Actinomyces in vitro and that the combination of the two drugs in usual dosage does not improve the results.

TABLE 2.—*Growth of Three Strains of Actinomyces in Vitro in the Presence of Sulfadiazine and Penicillin*

COMMENT

An analysis of the end results summarized in table 1 shows that both the sulfonamides and penicillin are highly effective drugs in the treatment of actinomycosis. Every case showed prompt improvement when the dosage was adequate. All patients, except the 2 who died, have remained either cured or with the process arrested for considerable periods, and the 2 patients who died (12 and 14) had at one time been improved on sulfonamide. Patient 12, with extensive pulmonary involvement, was improved on each short course of sulfadiazine, but it was not continued long enough on any occasion to be effective. Patient 14, with extensive liver and peritoneal abscesses, was improved by sulfathiazole and the process was arrested for several months after the drug was stopped, but the short course given in the terminal stage was ineffective.

Actinomyces bovis was found to be the infective organism in 12 of the 16 cases described; one was identified as Actinomyces asteroides. In 3 cases the exact species was not identified.

Of the 11 cervicofacial cases, there had been dental extractions in 9. In 6 there had been extractions before the infection became evident, and in 3 there had been extractions after the infection started. In the other 2 cases pus was draining from around one or more

8. Obtained from the Department of Bacteriology of the Stanford Medical School.

9. Keeney, E. L.; Ajello, Libero, and Lankford, Elsie: Studies on Common Pathogenic Fungi and on Actinomyces Bovis: III. In Vitro Effect of Penicillin, Bull. Johns Hopkins Hosp. 75:410 (Dec.) 1944.

teeth. These cases support the "endogenous" theory of infection, which suggests that the pathogenic organisms are more or less constantly present in the mouth and alimentary canal, rather than the "exogenous" theory, which suggests that the infective organisms are taken into the mouth accidentally and at once penetrate into the tissues. Also the occupations and mode of living of the patients were not such that frequent contact with infected cattle, straws and so on was possible, except for the 9 year old Indian girl.

The in vitro effects of penicillin and sulfadiazine corroborate the clinical impression that different strains of actinomycosis vary considerably in susceptibility to these drugs. These results suggest that, in adequate doses, sulfadiazine may be more effective clinically than penicillin but that both drugs are potent agents against actinomycosis.

CONCLUSIONS

1. Sixteen cases of actinomycosis were treated with sulfonamides or penicillin. These cases include 3 pulmonary, 2 abdominal and 11 of the cervicofacial types.

2. Of the 16 cases treated, 7 may be considered cured and 7 arrested, while 2 ended fatally.

3. In vitro tests corroborate the clinical impression of varying susceptibility of Actinomyces to sulfadiazine and penicillin and of the slightly greater efficacy of sulfadiazine in certain instances.

4. The results in these cases indicate that both penicillin and the sulfonamides are highly effective drugs in the treatment of actinomycosis.

REACTIONS TO 10,000 POOLED LIQUID HUMAN PLASMA TRANSFUSIONS

CAPTAIN EDWARD B. MILLER
AND
MAJOR LESLIE H. TISDALL
MEDICAL CORPS, ARMY OF THE UNITED STATES

The use of human blood plasma has become so prevalent that it is now firmly entrenched as an important part of our medical armamentarium. Since little has been reported concerning the reactions which may follow the administration of plasma,[1] it was felt that a detailed analysis of the extensive data collected at the Plasma Station of Fitzsimons General Hospital would add to the knowledge of this subject.

Each bottle of liquid plasma that is shipped from the Plasma Station is accompanied by a questionnaire which requests the pertinent information needed for a study of both beneficial results and reactions. The form is filled out by the attending physician and forwarded to our laboratory. Our report is based on an analysis of 10,000 such questionnaires returned from the 353 military hospitals within the continental United States provided with plasma by this station. The thousands of other plasma transfusions which have been given, using plasma supplied by this laboratory, and for which no questionnaires have been returned, have not been incorporated in this report.

From the Plasma Station, Fitzsimons General Hospital, Denver.

THEORETICAL TYPES OF REACTIONS

From a theoretical point of view there are several classes of reactions that may occur following plasma transfusions. These may be enumerated as follows:

1. Thermal or pyrogenic reactions.
2. Allergic reactions.
3. Hemolytic reactions.
4. Toxic reactions due to use of sodium citrate and merthiolate.
5. Transmission of infectious diseases from the donor.
6. Reactions due to bacterial contamination.
7. Pulmonary embolism.
8. Cardiac failure due to overloading of the circulation.
9. Miscellaneous reactions.

It is at once obvious that, in general, these classes of reactions are similar to those which may follow whole blood transfusions. However, because of the essential differences between whole blood and plasma, certain of these theoretical reactions have no practical bearing.

Thermal or Pyrogenic Reactions.—These reactions are characterized by chill and/or fever of a relatively transient nature. Such reactions are usually considered to be caused by either foreign substances or toxic products of bacterial growth called pyrogens.[2] Pyrogens are heat stable up to three hours of autoclaving and also water soluble. Hence their peculiar ability to produce reactions when present in a solution administered parenterally is in no way affected by the sterility of the solution, since they are not bacteria but the result of bacterial growth. Since mildly incompatible whole blood transfusions may result in uncomplicated chill and fever clinically indistinguishable from a pyrogenic reaction, we believe that the term thermal reaction is preferable despite the fact that the usual offending agent is pyrogenic. From the very method of the preparation of plasma it is evident that thermal reactions due to pyrogens can and do follow plasma transfusions.

Allergic Reactions.—The occurrence of allergic reactions following whole blood transfusions have been thoroughly detailed by Kilduffe and DeBakey.[3] According to them, these reactions fall into three types: the mild form characterized by urticaria of a more or less generalized nature, the moderately severe form evidenced by difficulty in breathing and loss of sphincteric control, and the severe type resembling anaphylactic shock. In our own experience only the mild and moderately severe forms of allergic reactions have been noted following plasma transfusions. Nevertheless the possibility of an anaphylactic reaction cannot be excluded, since the same factor responsible for such an occurrence following whole blood transfusion is probably also present in plasma.

The mechanism of allergic reactions following whole blood or plasma transfusions is not at all clear. In some cases the underlying cause is possibly due to the introduction of substances derived from ingested food by the donor to which the patient may be sensitive. In others, passive transfer of sensitivity to the patient may be the explanation. This will be taken up later under the analysis of allergic reactions.

2. Nelson, C. M.: The Cause of C[illegible] mous Therapy, J. A. M. A. **112**: 1,303 (April [illegible] L.: Cause and Elimination of Reactions After [illegible], Ann. Surg. **92**: 195 (Aug.) 1930.

of the signs and symptoms described occurring in this type of reaction.

As previously stated, we believe that the vast majority of these reactions are due to the presence of pyrogens introduced during either the procurement of the blood, the processing of plasma or the actual transfusion itself. The technic of procuring blood and of processing it into plasma is performed in a closed vacuum system in which the 4 per cent sodium citrate used as an anticoagulant and the 50 per cent dextrose in the pooling bottle have been found to be pyrogen free. The distilled water used in making the 1 per cent merthiolate solution is fresh and pyrogen free, as determined by the permanganate test. Obviously, then, if the solutions added to plasma are free of pyrogenic contamination, subsequent pyrogens must be introduced by means of the apparatus (tubing, needles and valves) used in the preparation and administration of plasma. Scrupulous care of all such apparatus is of the utmost importance. While other workers have emphasized this, we feel that the subject will bear repetition.

A definite routine has been established for the care of this apparatus. All needles, tubing and valves are cleaned immediately after use. No more than a few minutes are allowed to elapse between the time of use and the washing of these parts This is essential to prevent clotting and adherence of blood or plasma to the

apparatus. The parts are completely disassembled and washed twice with freshly distilled pyrogen free water under pressure. A third washing is performed with sterile pyrogen free saline solution freshly prepared. The needles are carefully styletted and the tubing is minutely scrutinized for any adherent blood or plasma. The valve parts are glycerinated and reassembled The entire set is put together and wrapped. The sets are then autoclaved, always within three hours from the time the apparatus was washed. This minimizes bacterial growth and therefore diminishes the occurrence of pyrogens. This method, while seemingly simple, has proved to be eminently satisfactory.

The foregoing procedure is strongly recommended for the proper care of the apparatus in the actual administration of plasma. Since the Plasma Station supplies plasma to more than 350 hospitals, it is difficult to exert control over this factor. Unquestionably many pyrogenic reactions occur because of this. To illustrate: Hospital A had 1 thermal reaction in 750 plasma transfusions, hospital B had 4 in 600, while hospital C had 6 in 150. It seems logical to assume, since all three hospitals are supplied with plasma made under standard conditions, that the difference in thermal reaction rate (hospital C having a rate thirty times greater than hospital A) could be attributed to local causes

In order to emphasize further the point that thermal reactions may be the result of factors not present in the actual processing of plasma, an analysis of this type of reaction by the pools involved was made as presented in table 3. Each 2,000 cc. pool is dispensed in four 500 cc. bottles.

It will be noted that there were 2 reactions in each of 18 pools. These 36 reactions may be ascribed to the plasma per se, even though in 14 of the pools two other

bottles from the same pool gave no reaction On the other hand, there was only 1 reaction in 116 pools of which either two or three bottles were administered without reaction. It would seem probable that these 116 reactions were not the result of pyrogens present at the time of processing the plasma but more likely were introduced during the administration by improperly cleaned intravenous sets. In addition there were single reactions in each of 48 pools in which one or no other reports were received. No decision can be made concerning this last group owing to lack of data Assuming the foregoing interpretation to be correct, the thermal reaction rate ascribable to plasma itself would be 0.84 per cent, which would include the group of 48 reactions with either one or no other reports Another explanation for the discrepancy in reactions to plasma derived from the same pools is that the sensitivity of different individuals to pyrogens may be quite variable. No information is available on this point, although the data may indicate such a possibility.

Allergic Reactions.—There were 105 reactions of the allergic type, of which all but 3 were urticarial in nature The usual urticarial reaction appeared during or soon after the infusion. The skin rash was either gener-

alized or localized When the latter type was present, the face was usually involved. Accompanying signs and symptoms, aside from itching of the skin, were rarely encountered. The other 3 cases of this group were ones of asthmatic breathing. These allergic reactions responded well to small doses of epinephrine

There are three possible mechanisms underlying allergic reactions: the transfer of substances derived from ingested food by the donor to which the recipient

is sensitive; passive transfer of sensitivity from donor to recipient; the sensitivity to common normal substances in plasma.

In an attempt to avoid the presence of possibly offending food derivatives in plasma, donors are placed on a semifasting diet consisting mainly of fluids and carbohydrates for the six hour period preceding the blood donation. The transfer of sensitivity is more difficult to control. Prospective donors with active allergic states are rejected. In a series of this type it is not possible to ascertain whether this selection of donors had any effect on the allergic reaction rate.

The data presented in table 5 consist of an analysis of allergic reactions from the same pools. As every allergic reaction must be ascribed to the plasma itself, it is of interest to note the sensitivity of the patients involved in these reactions to various pools. Nine pools were responsible for 20 reactions. Yet 12 pints of plasma from these same pools were given without any untoward result.

In table 6 the data of multiple allergic reactions in the same individuals are presented. The 105 allergic reactions were experienced by 81 different patients. Six of these patients suffered 24 reactions. One patient had as many as 7 allergic reactions to plasma from 5 different pools. Unfortunately it has been impossible to determine the allergic background of these patients.

It is on the basis of the foregoing data that we believe that many of the allergic reactions are due to the presence of a normal substance common to the plasma of many donors. An individual sensitivity to such substances by certain recipients can be postulated. Otherwise it is difficult to explain the case of 1 individual reacting to 7 bottles of plasma derived from 5 different pools. A probable factor in a certain small percentage is an idiosyncrasy to the citrate, glucose or merthiolate solution present in the plasma.

SUMMARY

In this series of 10,000 pooled liquid plasma transfusions, 296 reactions were reported, a reaction rate of 2.96 per cent. Of these, 200 were thermal reactions and 105 were allergic reactions. Eleven patients experienced combined reactions. There were 2 reactions of a miscellaneous nature. Eighty-nine (a total rate of 0.89 per cent) of the thermal reactions were believed to be ascribable to the plasma itself. Few of the reactions were severe in nature, and no fatalities or near fatalities attributable to the plasma transfusions were noted. There were no hemolytic reactions reported.

It is felt that thermal reactions, in the main, can be prevented. At one hospital where the transfusion apparatus was properly cleaned, one thermal reaction occurred in 750 plasma administrations.

While allergic reactions may be reduced in incidence by careful selection of donors, it is probable that they cannot be entirely eliminated, as there is considerable evidence to show that many of the reactions are due to a substance normally present in plasma to which certain individuals are sensitive. Certain chemical idiosyncrasies are also a factor.

We believe the closed vacuum technic used in obtaining whole blood and in the processing of plasma is the safest method in use from the standpoint of sterility. A contamination rate of approximately 1 per cent in the preparation of more than 70,000 pints of plasma supports this view.

Certain precautions must be observed in the use of plasma. The condition of the patient, indication for use, amount to be given and speed of administration are matters for the judgment of the attending physician. An adequate filter must always be used to prevent precipitated fibrin from entering the circulation and causing embolic phenomena. In the presence of a severe reaction of any type, the plasma transfusion should be discontinued. Subsequent plasma administrations to the same patient should be given from another pool. This is particularly important in the cases of allergic reactions.

CONCLUSIONS

1. Reactions following the administration of pooled liquid human plasma are chiefly of the thermal and allergic types.

2. Hemolytic reactions do not occur as the result of such plasma transfusions.

3. Reactions of the thermal type are largely preventable. Scrupulous and detailed attention to the proper cleansing of all apparatus used is essential in the prevention of pyrogen contamination.

4. Allergic reactions, because of the protein nature of allergies, cannot be prevented in the main.

5. The closed vacuum technic of procuring blood and of processing plasma is the ideal method.

6. The use of pooled liquid human plasma is eminently safe and attended with fairly infrequent reactions of relatively mild nature.

The First Mercury Thermometer.—The appealingly modest personal story of how he (Daniel Fahrenheit, 1686-1736) came in 1714 to invent the mercury thermometer and the scale of temperature by which his name is daily remembered in English speaking countries is told by a German instrument maker, Daniel Fahrenheit, native of Danzig and long resident in Holland. His was one of the early eighteenth century contributions to the study of the fascinating but complicated physical problem of heat, which will lead us through the work of Joseph Black, Lavoisier, Rumford, Joule, Helmholtz, Kelvin and Gibbs. Besides Fahrenheit, others who developed scales of temperature were R. A F de Reaumur, French naturalist (1683-1757) whose "Reaumur scale" (1730) is still used in many countries; Anders Celsius (1701-1744), Swedish astronomer at Uppsala, who first calibrated the centigrade thermometer (1742), divided into 100 degrees between the freezing and boiling points of water and universally employed in scientific work; and William Thomson, Lord Kelvin, who premised an "absolute scale" of temperature on which water boils at 373.7 degrees, freezes at 273.7 degrees and would—theoretically—cease to exist as water if it could ever be got down to absolute zero.—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co, Inc, 1945.

Clinical Notes, Suggestions and New Instruments

MENINGITIS DUE TO SALMONELLA PANAMA

MAJOR WILLIAM H WOOD JR, MAJOR FRANK H MAYFIELD AND CAPTAIN ARTHUR W FRISCH
MEDICAL CORPS ARMY OF THE UNITED STATES

Two cases of meningitis due to Salmonella panama comprise the material on which this paper is based Invasion of the human meninges by this organism is not common These cases are of especial interest, as the source of infection was traced to an attendant in the milk laboratory of the hospital in which the babies were born, and because 1 survived with sulfadiazine therapy

LITERATURE

Salmonella panama is a subgroup of the typhoid-paratyphoid group of bacteria (Topley and Wilson[1]) and is named for D E Salmon, the discoverer E O Jordan identified this particular strain (Salmonella panama) in 1934 as the cause of food poisoning among American soldiers in Panama In 1938 Schiff[2] described S panama as a cause of infectious diarrhea among infants in New York City A more complete account of infantile diarrhea by Abramson, Frant and Oldenbush[3] lists the Salmonella organisms as a prominent cause of this malady Harvey[4] in 1937 reviewed the literature of Salmonella suipestifer infections and added 21 new cases of his own which had occurred in and around Baltimore

Hormaeche and his associates[5] believe that Salmonella diarrhea occurs all over the world Infections due to this group of organisms are more frequent in children, though they do not always localize in the intestinal tract The state of the Salmonella problem has recently (1943) been reviewed most comprehensively by Bornstein[6] He proposes the terms Salmonella gastroenteritis (food poisoning), Salmonella fever (typhoidal type) and Salmonella septicemia for the three varieties of cases in human beings

The genus Salmonella comprises a group of more than one hundred strains of organisms which are pathogenic for animals and man The sources of infection are protean and include human carriers as well as a wide variety of animals Spread of infection occurs through handling poultry, eggs, meat, milk and other foods contaminated from animal sources, as well as certain rodents, flies and other insect vectors It is believed that most cases of Salmonella meningitis follow the septicemic form of the disease, salmonellosis, and the literature contains reports of cases of meningitis due to many different strains of this bacterium

Neter[7] quotes a review of the literature by Guerra, Peluffo and Aleppo published in 1940 in which he found that they had collected 56 case reports of purulent meningitis due to salmonellosis up to that time and adds 22 other cases collected since then, making a total of 78 cases He presents another of his own, a hydrocephalic child who died of meningitis due to Salmonella cholerae suis Bray and Meredith[8] also reported a case in a hydrocephalic child of 4½ months who died of Salmonella sandiego meningitis

It is the impression of most investigators that Salmonella infection is apt to prove fatal to the very young, to debilitated patients or to those having a mixed infection Yet Ravitch and Washington's[9] patient, a 4½ year old Negro girl, developed Salmonella suipestifer (also called cholerae suis) septicemia and meningitis complicating meningococcic septicemia and meningitis She survived, and her survival was attributed by the authors to the preceding meningeal reaction produced by the meningococcus and its antiserum A 7 year old girl observed by Neter[10] was cured of meningococcic meningitis and Salmonella cholerae suis bacteremia by sulfathiazole Another patient studied by Neter[11] suffered from S cholerae suis bacteremia complicating scarlet fever This patient recovered on sulfanilamide and sulfadiazine medication

Katsampes and Bradford[12] reported the recovery of a month old infant suffering from Salmonella panama meningitis with sulfapyridine Wilsdon and Gibson[13] also recorded the case of a man aged 61 who had meningitis due to Salmonella london His cerebrospinal fluid was sterilized by sulfapyridine though he subsequently died of hypostatic pneumonia Patterson's[14] 2 patients with paratyphoid B (Salmonella paratyphi B) meningitis recovered after sulfapyridine and sulfathiazole medication He concluded that neither drug appeared to be specific but that sulfathiazole was probably to be preferred until some better drug was discovered Hollis and Barron[15] had a fatality in a child with meningitis of the Salmonella oranienburg type They stated that sulfonamide medication is effective in certain types of Salmonella meningitis Of 9 patients who recovered from this condition, out of a group of 53, sulfonamides were used in 5 In the other 44 sulfonamides were used in only 2

In trying the effect of sulfaguanidine on the various strains of dysentery and Salmonella organisms, Bornstein and Strauss[16] concluded that this drug was effective against bacillary dysentery and against S paratyphi A and S cholerae suis though ineffective against other organisms of the Salmonella group Sulfathiazole and sulfadiazine have been reported to be effective against other cases of septicemia[17] and a urinary tract infection[18] due to Salmonella organisms When confronted with a case of purulent meningitis one is still justified in beginning therapy with one of the sulfonamides, preferably sulfadiazine or sulfathiazole Penicillin has little if any effect on the salmonella group

REPORT OF CASES

CASE 1.—T a white male infant, was brought to the hospital on the twenty third day of life After a normal full term pregnancy he was delivered with the aid of midforceps on Jan 24, 1944 He seemed to be vigorous and healthy, weighing 8 pounds 7½ ounces (3,840 Gm) His course during the ensuing thirteen days was not remarkable As his mother had a breast infection, he was given the usual formula of evaporated milk, boiled water and dextrimaltose He nursed well and gained weight normally and was allowed to go home with his mother on February 6

During the succeeding ten days all went well, but on February 16 he exhibited unusual twitchings and slight generalized convulsive movements, and it was thought that he had an elevation of temperature, consequently he was brought t

see us. The family history and past history were irrelevant. The examination was negative save for a generalized convulsion and temperature of 102 F. He was put in a local hospital and observed for the rest of that day. The next day his temperature was 104 F., and as convulsions had continued at intervals a lumbar puncture was performed even though the fontanel was soft and level and the neurologic examination otherwise negative. Purulent spinal fluid was released under

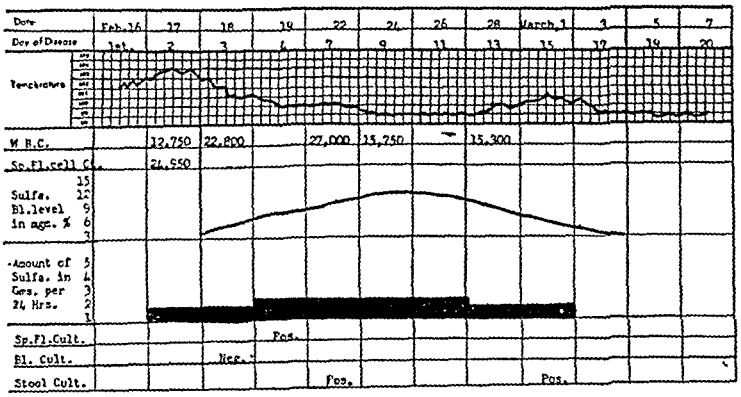

Chart 1.—Course in case 1.

normal pressure. There were 24,950 white blood cells present (95 per cent polymorphonuclears).

Sulfadiazine therapy was instituted immediately. The drug was given by mouth, as the patient was not vomiting. The daily dose varied between 1 and 1.5 Gm. to maintain a blood level of 6 to 10 mg. per hundred cubic centimeters. His clinical response was good. The elevation of temperature subsided gradually during the succeeding several days, and white blood cells, which varied between 22,000 and 27,000 early in the disease, subsided to 15,000 (chart 1).

By February 19 a gram negative motile rod had grown from the spinal fluid culture, later identified as Salmonella panama. The same organism grew from the stool culture but not from the blood. Sulfadiazine was continued till March 1. On that day the patient had begun to vomit, slight puffiness of the eyelids appeared, and the temperature rose to 101 F. Fearing renal damage, the drug was stopped immediately. Subsequent urine examinations were normal, the edema and vomiting quickly disappeared and the temperature subsided. Attempts to obtain cerebrospinal fluid for follow-up examinations were unsuccessful from the lumbar route. As the clinical condition of the patient was so good, it seemed wise not to attempt cisternal or ventricular taps at this time.

He left the hospital March 7 and since that time has continued to do well at home.[19]

CASE 2.—H., a white female infant, was first seen on the twenty-first day of life. She was born in the same hospital, spontaneously at term, Jan. 28, 1944. Her birth weight was 8 pounds 8½ ounces (3,860 Gm.) and she seemed to be normal in every way. She was put to the breast but required additional feedings consisting of evaporated milk, boiled water and dextrimaltose. As the maternity ward was crowded, and as she and her mother were so well, they went home in an ambulance on the fifth day of the puerperium.

On February 14 she did not seem as well as usual. She cried much of the time and refused to eat. A doctor said she had a cold and treated her symptomatically. On February 16 she twitched occasionally. Gradually the hyperirritability increased and she was brought to us on February 18, four days after the onset of the present illness.

The family history and past history were irrelevant. The history as given was elicited. On examination it was apparent that her temperature was moderately elevated and that she was hyperirritable, as evidenced by clonic convulsive movements. The fontanel was full, though not bulging. A lumbar puncture was attempted but no fluid could be obtained. The next day one of us (F. H. M.) obtained a few drops of purulent cerebrospinal fluid from the cistern. From this, the same organism was ultimately isolated (Salmonella panama). As in the first patient, S. panama was also recovered from stool, but not from blood cultures.

This child also was placed on sulfadiazine medication, an average daily intake of 1.5 Gm. producing an average blood level of 8 mg. per hundred cubic centimeters. During the first week her temperature subsided from 103 to 100 F., though the white blood cells remained up around 18,000 to 20,000 per cubic millimeter till March 1. During this period she required small doses of phenobarbital to control her convulsive tendency.

On March 3 a ventricular tap showed the cerebrospinal fluid to be slightly cloudy. It contained 1,120 white blood cells (42 per cent polymorphonuclears and 58 per cent lymphocytes), 18 mg. of sugar per hundred cubic centimeters, 1,013 mg. of protein per hundred cubic centimeters and 11.6 mg. of sulfadiazine per hundred cubic centimeters. By March 20 her temperature averaged 99 F. and the white blood cells 8,500 per cubic millimeter. Though she did not seem toxic (in fact, her weight gain had been satisfactory throughout) the fontanel was bulging, and 45 cc. of clear cerebrospinal fluid was withdrawn from the ventricles. This fluid contained 150 white blood cells per cubic millimeter, 9 mg. of sugar, 1,025 mg. of protein and 4 mg. of sulfadiazine per hundred cubic centimeters. The culture remained sterile (chart 2).

Feeling that she was over the infectious or septic phase of her disease, though fearing hydrocephaly, we discontinued medication and allowed the patient to go home. She was brought in every three or four days. On these visits the head always was tense, and 50 to 100 cc. of clear sterile ventricular fluid containing about 100 lymphocytes was withdrawn. The circumference of her head gradually increased to 17⅞ inches.

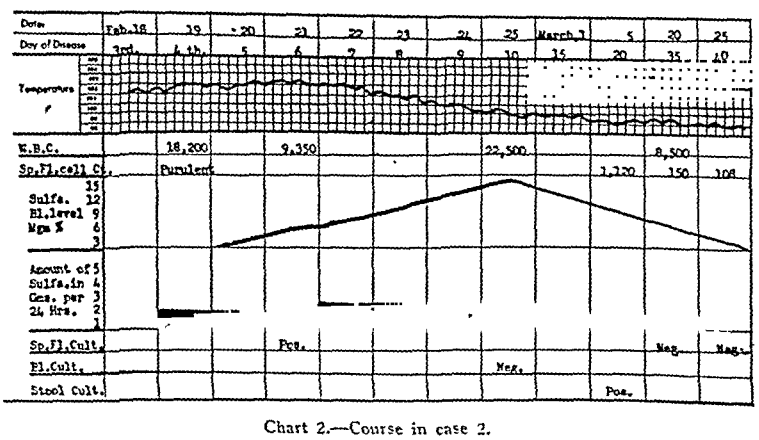

Chart 2.—Course in case 2.

Owing to lack of proper surgical facilities she was referred to Dr. A. Earl Walker of the University of Chicago on April 18 for some possible palliative surgical procedure. Intervention was deemed unwise, and shortly thereafter the baby died.

Postmortem examination revealed "chronic hyperplastic arachnoiditis and ependymitis with severe internal hydrocephalus due to occlusion of the foramen of Munro on the right and stenosis of the foramen of Munro on the left, with bilateral occlusion of the foramens of Luschka and Magendie. The picture is compatible with the end result of Salmonella meningitis."

19. Since this article was written we have heard indirectly that the patient remained well until July 26, on which date he is said to have received a third injection of pertussis vaccine. A stormy illness followed and he died two days later, four months and three weeks after leaving the hospital. The attending physician failed to obtain cultures of blood or of cerebrospinal fluid, but such a clinical course would not suggest that salmonellosis played a part in this last illness.

COMMENT

The 2 cases here reported are of unusual interest as the 2 infants were born at the same hospital within four days of each other. Both were healthy full term babies, cared for in the same nursery and given the same formula. They remained well till the twenty-third and seventeenth days of life, respectively, suggesting a two to three week incubation period.

The same infecting organism, Salmonella panama, was recovered from the spinal fluid and stool cultures of the 2 patients. Though blood cultures remained sterile, and though neither child suffered gastroenteritis, the port of entry was most likely the enteron, with subsequent infection of the meninges via the blood.

So many points of similarity suggested a common source of infection for these 2 patients. The state public health department of Michigan later isolated the identical organism from the stools of an attendant in the milk laboratory of the hospital. It seems reasonable to presume that this person was the carrier from whom these infants received their infection.

Routine stool cultures done on all babies who had been in the nursery around this time revealed the presence of a rather widespread epidemic due to Salmonella panama. A large number had mild infectious diarrhea of short duration. Approximately an equal number showed no symptoms. Three such carriers had positive stool cultures for several months after the initial infection.

When roughly tested on ordinary culture mediums, both cultures were found to be resistant to concentrations as high as 20 mg. of sulfathiazole and of sulfadiazine per hundred cubic centimeters. In view of the favorable clinical result obtained, one of us (A. W. F.) again studied the cultures by a quantitative method, as follows: Approximately 500 organisms per cubic centimeter were inoculated into a medium composed of 10 per cent rabbit serum and Tyrode's solution (p_H 7.4) containing 5 mg. of sulfadiazine per hundred cubic centimeters. Appropriate samples were plated out at various intervals and the number of colonies compared with the control tubes to which no drug had been added. Both strains of S. panama were relatively little affected during the early logarithmic growth phase, but by the end of sixteen hours a 50 per cent reduction in the population of one culture (case 1) and an 80 per cent decrease in the second (case 2) was observed in the presence of 5 mg. of sulfadiazine per hundred cubic centimeters. These data suggested that under favorable conditions the organisms were also susceptible to the in vitro action of sulfonamide drugs.

Sulfonamide medication was employed as is recommended by all authorities, at least until the causative organism of purulent meningitis is established. When the etiologic factor was found to be a Salmonella bacterium a review of the literature failed to offer a better mode of therapy. Penicillin seems to have no effect on this group of organisms, and our particular strain grew in the presence of 5 and 10 units of penicillin.

We add these 2 cases of S. panama meningitis to the growing list of Salmonella infections, as we feel that the first patient was definitely cured by the treatment employed and that the second patient was cured of the septic process only to succumb to an internal hydrocephalus, an aseptic pathologic process.

SUMMARY

Two cases of meningitis due to Salmonella panama were observed in infants 3 weeks of age who were born within four days of each other at the same hospital. The source of infection is believed to have been a carrier of this organism who worked in the hospital milk laboratory. The period of exposure ranged from five to thirteen days. The onset of symptoms occurred in seventeen to twenty-three days.

Sulfadiazine was used for periods ranging from fifteen to thirty-four days. One patient survived with this treatment, but the second died of an internal hydrocephalus due to an inflammatory obstruction, though the cerebrospinal fluid remained sterile.

We recommend routine stool cultures on all hospital attendants who come in contact with infants and debilitated patients.

Special Article

This article has been read by the majority of the members of the Council on Medical Service and Public Relations and is published with the approval of the Council for the information that it contains relating to the factors underlying the demand for federal sickness insurance.

E. J. McCormick, M.D., *Chairman.*

HEALTH INSURANCE

AN INQUIRY INTO SOME OF THE FACTORS AND FORCES UNDERLYING THE DEMAND FOR A COMPULSORY SYSTEM

CARL W. STROW, Research Consultant
AND
GERHARD HIRSCHFELD, Director
Research Council for Economic Security
CHICAGO

During the legislative sessions of 1945, more than thirty measures proposing cash sickness benefit plans or compulsory health insurance systems were introduced in twelve state legislatures. Other bills called for studies of health insurance. In Congress a number of bills were introduced providing for some sort of medical care or sickness benefits. No other year has seen such a demand for compulsory health insurance.

Compulsory health insurance, briefly, is a system by which medical and hospital care would be available to all who desire it, the cost being paid by employers, employees and, possibly, government. Compulsion would stem from the fact that everybody would be required to pay taxes regardless of whether or not he sought medical care. Cash sickness benefits refers to a system by which those covered would be entitled to weekly benefit payments in case of illness. The purpose is to make up partly for loss in wages or salaries during such time. A comprehensive system may offer both medical and hospital care as well as cash benefits, and there have been a few such proposals.

Behind the demand for compulsory systems of medical and hospital care or cash benefits, or both, is the belief that present medical treatment is inadequate; that this results in large losses that could be prevented; that an economic barrier exists between the needs of the average patient and the medical services available.[1]

However, more careful inquiry will reveal that the demand for compulsory health insurance has been more consistent and more pronounced in some states than in others. New York, for instance, has had no fewer than twenty-seven health insurance bills introduced in the legislature between 1935 and 1945. Yet New York has far better medical and hospital facilities, as well as provision for social services, than the average state. On the other hand, such states as Mississippi, Georgia, Alabama, Arkansas and the Carolinas, where the need for medical care is most acute, have practically no organized demand for compulsory health insurance.

Who then is responsible for the demand? Is it the sick and the poor who want it because they need it? Is it the government, trying to gain political benefit? Is it organized groups, such as industrial labor? Is it enterprise? What is behind the demand—social pressure, economic conditions, political interests? What is

1. The Debaters' Digest, May 1940.

the need for medical care and what its estimated cost? Is prevalent disease the only problem, or shall attention be given to potential illness? What are some of the basic factors that should be considered in a constructive health program?

How much is known about the actual conditions underlying our national health problem? Should a decision be made now or should more time be given to research and study? While this article cannot give the answers, it attempts to shed some light on the various problems in order that a better view may be obtained on the subject of compulsory health insurance.

HISTORY

The social reform movement early in the century played an important part in proposing state health insurance. It was supported by such "social reformers" as Louis D. Brandeis, associate justice of the Supreme Court of the United States; Lillian D. Wald, head of Henry Street Settlement, New York City; Charles R. Henderson, head of the Department of Practical Sociology, University of Chicago; Edward T. Devine, professor of social economy, Columbia University, and John B. Andrews, secretary of the American Association for Labor Legislation. Another group included economists such as John R. Commons, professor of economics, University of Wisconsin; Henry R. Seager, professor of political economy, Columbia University, and Joseph P. Chamberlain, professor of public law, Columbia University

In 1910 the Russell Sage Foundation sent Frankel and Dawson to study European systems of social insurance. Their report did much to stimulate the movement in this country. In 1911 Brandeis advanced the idea of compulsory social insurance against sickness before the annual meeting of the National Conference on Charities and Corrections. The next year the American Association for Labor Legislation set up a Committee on Social Insurance. This committee, together with one from the American Medical Association, drafted a Model Sickness Insurance Bill in 1915, called the "Standard Bill." It was introduced in the Massachusetts, New Jersey and New York state legislatures.

During the 1915-1921 period, eleven legislative commissions were appointed to study and report on the proposal for state health insurance. Six of these—two from California and one each from Massachusetts, New Jersey, Ohio and Pennsylvania—submitted recommendations in favor of the proposed plan while five—from Illinois, Connecticut, Massachusetts, Pennsylvania and Wisconsin—reported unfavorably. Bills providing for state health insurance were introduced into the legislatures of fifteen states but were defeated in all cases. The "Standard Bill" passed the New York state senate but was defeated in the house. By 1921 the movement had practically ceased and little more was heard of it for over a decade.

In more recent years the first major event stimulating discussion of and proposals for compulsory health insurance was a publication in 1932 of the final reports of the Committee on the Costs of Medical Care. Composed of physicians, social scientists and laymen, this committee had begun its investigations in 1927 with funds provided by the Rockefeller Foundation, the Russell Sage Foundation and other organizations.

In 1934 the American Association for Labor Legislation sent circular letters to individuals over the country asking them to send telegrams to the Secretary of Labor and the President of the United States urging on them the need for state compulsory health insurance. The American Association for Social Security has been the chief sponsor of health insurance in the states. In 1935 it formulated the Model Bill, largely under the leadership of Abraham Epstein.

Since 1935 and including 1945, 102 bills have been introduced into the legislatures of twenty states, with success only in Rhode Island, in 1942. The passage of the National Social Security Act in 1935 was largely responsible for the increased activity. From then on the social insurance movement accelerated, with the subject of health insurance coming in for special consideration. The largest number of bills, previous to 1945, appeared in 1939, when the Wagner Bill was introduced in Congress.

HEALTH SURVEYS

The Committee on the Costs of Medical Care found that for an average day 2 per cent of the working population of the United States were disabled by sickness, with an annual wage loss of $1,000,000,000 in 1928-1929. The people of this country suffer from one to two disabling illnesses per person each year; female workers lose from eight to twelve days per year; male workers seven to nine days each year; school children average seven or more days of illness each year.

* As of April 22, 1945
Source Research Council for Economic Security, Chicago 3

This table illustrates the rising trend in the number of compulsory health insurance bills introduced in state legislatures While in the ten year period from 1935 to 1944 the total number of such bills amounted to sixty six, the current year has seen no fewer than thirty six bills introduced in state legislatures An interesting sidelight is provided by the fact that the states ranking highest in cultural traits, that is, in economic and social development, boast the largest number of health insurance bills.

Distribution of services was unequal. Lacking in rural areas, towns and small cities, it was also unevenly distributed among individuals and classes. The 10.3 per cent of the population suffering the largest amount of sickness paid 41.2 per cent of total costs of medical services. The committee concluded that under existing methods of payment it is impossible for 99 per cent of families to set aside a reasonable reserve for medical expense.

Another survey was conducted by the United States Public Health Service in 1935-1936 It aroused much discussion and was partly responsible for the National Health Conference in 1938, composed of 170 delegates

from labor, farming, industry, civic clubs, social work, public welfare, medicine, nursing and hospitals.

The comparison summarized in table 2 shows some of the difficulties encountered in the investigation of the need for and cost of medical care. There is wide differentiation between the income groups, the number

TABLE 2.—*Comparative Summary of Health Surveys in the United States on Sickness and Medical Care*

	California Medical Economic Survey 1933-34	Committee on Costs of Medical Care 1928-31	National Health Survey 1935-36	U. S. Public Health Survey 1928-31
Illnesses per thousand of population	928 Income $1,200-$1,999	910 Income $1,200-$1,999	Not given	823
Disabling illnesses per thousand	492 Income $1,200-$1,999	488	172 7 days and over	492
Hospitalized illnesses per thousand	85 Income $600-$1,199	62 Income $1,200 less	46.7	59
Average days of disabling illness per person	16.30 Males	6.40 Income $1,200-$1,999	9.83	7.70
Cost of medical care per person	$24.33	$22.58	$16.00	Not given
Cost of medical care per family	$79.25	$89.53	$64.00	Not given
Per cent of illnesses receiving medical care	73.9 Income $1,200-$1,999	71.4 Income $1,200-$1,999	81.0	Not given

of hospitalized illnesses, the average days of disabling illness and the cost of medical care. Although four careful surveys have been made, they have not yielded conclusive evidence of the size or definite knowledge of the nature of our national health problem.

PRIVATE PROTECTION

Moreover, these surveys hardly take into consideration two major causes for the increasing demand for compulsory health insurance: first the progress of medical science, second the development of private insurance.

The American medical miracle increased the life span by about fifteen years between 1900 and 1944. New remedies and public health measures have reduced substantially the death rate from typhoid, scarlet fever, whooping cough, tuberculosis, dysentery and malaria, diarrhea and many other diseases. "Without such advances, these nine diseases alone would have taken ten times more American lives during the past forty years than were lost by all the United States armies during our entire history, until 1941." [2] These achievements have been publicized widely and have no doubt been appropriated by the thinking of every individual. From the knowledge of it the demand for modern medical services has been but a small step.

Social insurance probably would not have appeared so conspicuously on the field of social reform had the general concept of insurance not been developed greatly and become known more widely during the last twenty years. The introduction of group insurance, the supplementing of old age and survivors' insurance, the idea of social budgeting have contributed substantially to a greater appreciation of the principle of insurance. Accompanying charts show the amazing growth of such services as health and accident insurance (chart 1) and Blue Cross plans (chart 2) during the last decade. According to the Health and Accident Underwriters Conference, at the end of 1944 more than 40,000,000 persons were covered under some form of health and accident insurance, a fivefold increase over 1934, when about 8,000,000 people were insured. The increase in premium value has kept pace with the increase in coverage. From $69,000,000 in 1919, premium value increased to $525,000,000 in 1944, when benefit payments to policyholders increased in proportion.

Operating in forty-two states with a population of over 110 million, eighty-two Blue Cross plans have 17,500,000 members enrolled under 7,500,000 contracts. This is over 12 per cent of the total population, or nearly 16 per cent of the population in the states covered. It is estimated that hospitals with more than 90 per cent of all nongovernment beds are now enrolled in Blue Cross plans.

Another form of private protection is prepaid medical care, which covers at present between 4,000,000 and 5,000,000 people. Although much remains to be done in developing and perfecting this service, such states as Washington, Oregon, California and Michigan have between 9 and 16 per cent of their populations thus covered. A widely organized system of prepaid medical care would go far toward solving the medical part of our national health program.

Benefit payments on account of sickness and disability by national and international labor unions totaled about $50,000,000 between 1933 and 1944.[3] Fraternal societies have sickness benefit schemes in operation covering more than 4,000,000 members.

These are some of the forms of voluntary protection. Of course, there are many others, such as life insurance, soldiers' insurance, industrial pensions, community chests, homes for the aged, retirement funds, private savings including war bonds and workmen's compensation.

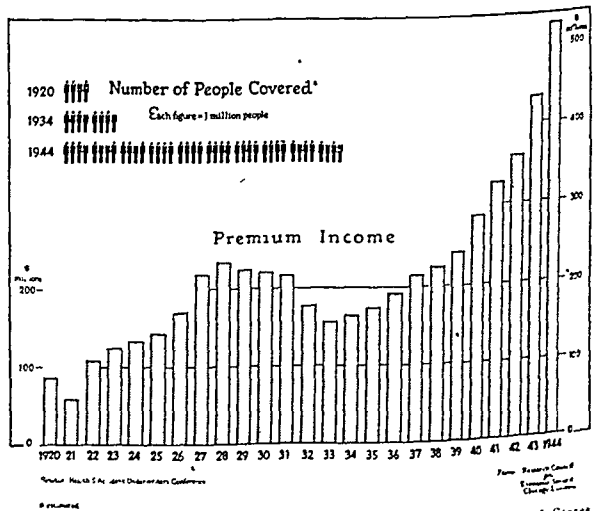

Chart 1.—Growth of health and accident business in the United States 1920-1944.

It is probably no exaggeration to estimate the face value of all private protection close to the aggregate of our national wealth, i. e. in excess of $350,000,000,000. Although this estimate is bolstered by the favorable conditions of the present period of prosperity, it is still

2. Medical Care for Everybody? American Association of University Women, published in 1945.

3. Proceedings of American Federation of Labor Convention

likely that even under less favorable conditions the total amount of private protection would not be less than $250,000,000,000.

Perhaps it would be natural to expect the demand for compulsory health insurance to go down as the amount of private insurance protection goes up. But this expectation is not fulfilled. Present trends do not

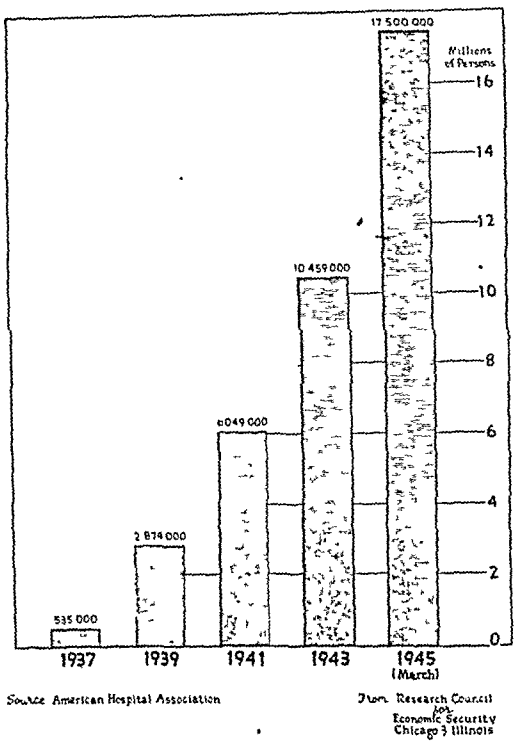

Chart 2.—Enrolment in Blue Cross plans, 1937-1945.

seem to support this contention. The demand for compulsory health insurance has never been louder or more insistent. Yet the amount of private protection has never been greater. The implication is that the demand is not guided primarily by the medical needs and that even a perfect system of private coverage would not still the demand for a compulsory system.

PUBLIC OPINION

While in the end the public will decide what form of health insurance the country shall have, in the actual debate the public has remained in the background. From the standpoint of organized expression it may be said that the line-up of groups favoring or opposing compulsory health insurance has changed little during the last thirty years. Generally in favor are organized labor, the reform groups, philanthropic organizations, the Social Security Board and other groups. Opponents to a comprehensive compulsory system of health insurance under federal administration are found among insurance companies, manufacturers, commercial organizations, the medical profession and those responsible for the entrepreneurial system and, beyond that, dependent in their operations on the principles of free and individual enterprise.

It is difficult to form an exact conclusion on what the public thinks of the problem of health insurance. Public opinion polls would indicate that the public favors health insurance. However, this depends on the form in which the question is submitted. If it emphasizes benefits, public opinion favors health insurance. But when the question emphasizes the financial cost, the necessary tax burden and the economic consequence in general, the public seems to be less sure about the desirability of a compulsory system.

That public thinking on the matter is closely allied with economic conditions is shown in the accompanying chart. The number of articles taken from the "Reader's Guide to Periodical Literature" from 1932 to 1944 shows that the interest in health insurance rises considerably in a period of depression and leads up to legislative action. This is clearly expressed in the line from 1933 to 1934, the peak of which is followed by enactment of the Social Security Act in 1935. Again, from 1937 to 1938 the line rises and leads up to the extension of the Social Security Act in 1939. Since we have had the Beveridge plan, the Delano Report, the Wagner-Murray-Dingell Bill, and other recommendations for social security legislation, the line is rising without a break.

NEED FOR MEDICAL CARE

Notwithstanding the large amount of voluntary protection against illness, there is no disagreement among the advocates of compulsory health insurance, as well as the opponents, as to the need for better medical care. The disagreement is about the form, the administration, coverage, benefits and many other details. Moreover, the term "need for medical care" is by no means understood alike by all concerned. For one thing, complete statistics on the extent of disease, prevalent and potential, are lacking in practically every one of the forty-eight states. For another, the need for medical care is relative, changing with economic circumstances, physical

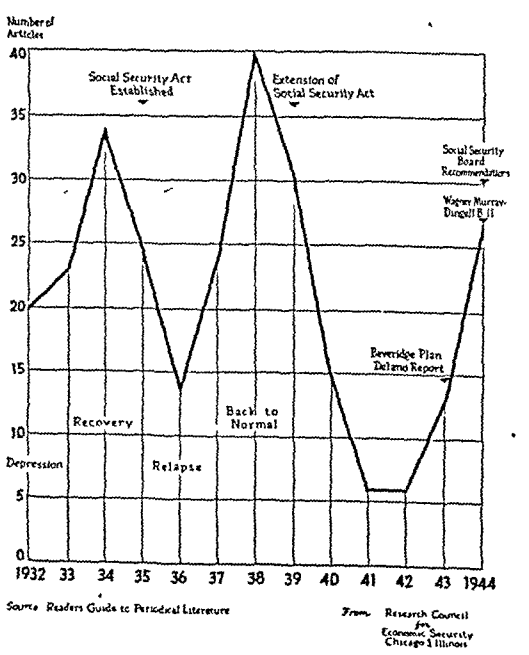

Chart 3.—Number of articles in periodicals on economic and political aspects of medical care, 1932-1944

conditions and personal attitudes. A man working on a farm may think nothing of a cold that bothers him for a few days. He may keep right on working. In contrast, a woman living in the city may be bothered so much by a cold that she feels obliged to consult a physician or even go to a hospital. What is the absolute

need for medical care in the one case and in the other? Two persons suffering from the same kind of disease but possessing different degrees of intelligence may go about their treatment in different ways. The well informed man may seek medical consultation early and find relief quickly. Another may postpone action until his case not only requires a long period of hospitalization but invites complications calling for more elaborate and expensive treatment than was justified originally.

In addition to this problem which concerns the individual there are other problems which go beyond the personal aspects. The health problem differs in virtually every state. In California, communicable diseases account for a major share of reported illnesses. In 1940 chickenpox, whooping cough, mumps, measles and other contagious diseases accounted for about two thirds of all cases reported. In Mississippi influenza, syphilis, malaria, gonorrhea and dysentery are high on the list of reported illnesses. Mississippi's health problem is largely a Negro problem, with illness rates higher among Negroes than among white persons, and death rates from all diseases except cancer, heart disease and suicide between 20 and 50 per cent higher than those for white persons. In New York cancer, syphilis, tuberculosis and pneumonia are the important health problems. In Wisconsin, again, epidemic illness, chickenpox, measles and mumps claim the largest share of reported illnesses.

SANITATION AND HYGIENE

This contrast in leading causes of illness makes it difficult to analyze the health problem of our nation and makes it dangerous to generalize on the requirements for better medical care. But there is still another problem that should be given serious consideration. It is the lack of sanitation and hygiene as a major contributing factor to disease.

Taking the country as a whole, nearly 50 per cent of the population is in need of sewerage systems.[4] In a state like Mississippi, 78 per cent of the population are without benefit of sewerage, followed by Arkansas and Idaho with 74 per cent, South Carolina with 72 per cent and Utah with 71 per cent. In the matter of water supply, 12.5 per cent of all rural dwellings lacked water supply within 50 feet of the house.[5] North Dakota with 39 per cent, New Mexico with 30 per cent, Arizona with 27 per cent, South Dakota with 26 per cent and Montana with 25 per cent headed the list.

An equally unfavorable picture is found in the field of housing. Before the war 18.3 per cent of all dwelling units throughout the country were substandard buildings, i. e. in need of major repairs. Arkansas (39.1 per cent), Alabama (37.0 per cent), Oklahoma (34.5 per cent), North Dakota (33.7 per cent) and Mississippi (33.6 per cent) were the five leading states in this respect.[6] It is widely agreed that lack of sewerage, water supply, sanitary housing facilities and equipment breed disease and probably account for a major share of the large amount of potential disease, little of which is reported or dealt with. Nevertheless here is a very real and vital part of our national health problem which must be taken into consideration if a satisfactory and lasting solution of that problem is to be found.

COST

Even if the exact nature and extent of the need for medical care were known, it still would not be enough to set up a definite health insurance program. The next step would be to ascertain the cost of a program developed from this information. Obviously, since the exact need is not known, neither can be the cost. In spite of this lack of knowledge, the advocates of compulsory health insurance have not hesitated to make definite recommendations.

According to the Insurance Economics Society of America fourteen compulsory health insurance measures were introduced in the legislatures of six states in 1945. Of these, four were compulsory health insurance measures providing medical care, hospitalization and other services to the employed and their dependents, as well as cash benefits to the employed during disability. Tax rates proposed varied from 2 per cent to 4 per cent of the payroll up to $3,000. The other ten proposals provided medical care, hospitalization and other services only. Tax rates varied from 2 per cent of the payroll up to $3,000 to 3 per cent of the payroll up to $5,000.

In other words, it is apparently assumed that a payroll tax of 3 per cent or less would be adequate. But it is a question whether this rate would be sufficient to cover the cost of a comprehensive system of medical care, hospitalization and cash sickness plans.

In explaining his "Model Bill," Abraham Epstein, one of the best authorities on social insurance in the United States, wrote as follows:

> Available data indicate that an amount equal to about 6 per cent of the wages of all insured persons is necessary for a sound health insurance program. Of the total, 4.5 per cent is needed for the health services with adequate remuneration to the medical professions, and 1.5 per cent for the cash benefits.

In connection with the proposed system of medical and hospital insurance in California, the California State Chamber of Commerce estimated "that the cost of care which would be made available under the governor's bill would require an average expenditure of 4.5 per cent of income."[7]

The Heller Committee of the University of California, which made detailed studies of incomes and expenditures of families in the Bay Region, estimated that a minimum of 5 per cent of income is needed for medical service even if such service is purchased at minimum cost through a group prepayment plan.

In Mississippi the cost of compulsory health insurance as of 1940 has been estimated by the Research Council for Economic Security at about $29,000,000 a year. This would require a tax of more than 6 per cent of all income payments received by the people in the state. If administrative costs were added, a tax of 7 per cent would probably be necessary.

In New York State, which has a comparatively high per capita income, it is estimated that a 5 per cent payroll tax would come close to financing a system of compulsory health insurance. However, if the cost of medical services should be higher than when the individual bears the cost himself, a 6 per cent tax would probably be necessary.[8]

Legislative bills in Wisconsin proposed a 4 per cent tax with which to finance a compulsory health insurance system. Before the war this rate would have yielded $28,000,000. If 10 per cent should be allowed for administrative costs and 5 per cent for reserve, the net

7. Health Insurance for California? February 1945, p. 26.
8. Research Council for Economic Security.

amount available for benefit payments would be about $23,000,000. In contrast, the amount needed for benefits in 1940, on the basis of a $20 annual medical cost per person, would have been over $32,000,000. Apparently a tax rate of between 5.5 and 6 per cent would be required to finance a comprehensive health insurance plan.[8]

From this brief survey of the cost of proposed health insurance plans it is evident that in most cases a 3 per cent payroll tax is inadequate. A more realistic appraisal would point to a tax rate of between 5 and 7 per cent of payrolls, and even this rate would only be sufficient to finance a system of medical and hospital care. Additional appropriations would be required for the financing of a cash sickness plan such as is in operation in the state of Rhode Island and as has been proposed in other states. There is good reason to believe that the payroll tax rate required for the financing of a system of compulsory hospital and medical care plus a cash sickness plan would be close to 7 per cent. It is against such a rate of taxation that the true cost of a compulsory system of health insurance should be determined and the effects of that cost on the state economy, on wages and enterprise, on investment, on buying power and on other factors should be evaluated.

Moreover, cost factors are elastic. Expenditures under a compulsory health insurance system are probably higher in periods of depression than of prosperity. When employment is abundant and the wage level high, people do not take time out to be sick unless they have to; it loses them substantial income. But when people, through lack of employment and low wages, risk little or no loss of income by staying home and claiming health or sickness insurance, the claim rate rises substantially.

Experience both at home and abroad shows that the claim rate goes up as prosperity goes down. This is not to imply that people submit claims under false pretenses. However, it is a statistical record, viz. the recent history of the Cash Sickness Plan in Rhode Island as well as the much longer experience of compulsory health insurance in Germany, Great Britain and other countries; also in the public works experience in our own country during the thirties that people take advantage of benefits offered under a compulsory system. If the records do not necessarily indicate that people claim benefits to which they are not entitled, nevertheless they show that "opinionated sickness" makes for a tremendous cost of compulsory health insurance. No doubt this trend is, at least in part, responsible for the fact that in Germany expenditures of the compulsory sickness insurance system rose from 12.16 reichsmarks per member in 1885 to 93.64 reichsmarks in 1939, while in Great Britain they rose from £0/17/10 in 1912 to £2/6/– in 1927. There is little reason to assume that a compulsory system of health insurance in our own country or in any state would not follow a similar pattern.

It is a dangerous practice to rely too much on a fixed rate of taxation. While a rate can be fixed, the amount of revenue cannot. A 3 per cent payroll tax levied under conditions of full employment and high wages yields a return substantially larger than the same tax would yield in a period of widespread unemployment and low wages. In determining revenue one must bear close watch on the wide fluctuations of economic activity in general and of unemployment and wages in particular.

THE PART OF LABOR

Our national health problem, then, is not a simple one. However, the various difficulties have not deterred the interested parties from advancing their compulsory health insurance proposals at every opportunity, in the belief that this will go a long way toward solving that problem. In doing so perhaps they have not been guided primarily by the need for medical care or the cost or the fact that there exists a good deal of voluntary protection. Apparently other considerations have played a decisive part in the demand for compulsory health insurance. Where does that demand originate? And what are the times and conditions most conducive to it?

Periods of depression which influence the demand for compulsory health insurance also contribute greatly to the growth of organized labor. Within ten years, membership in the two leading unions, the American Federation of Labor and the Congress of Industrial Organizations, has risen from less than 3,000,000 to more than 13,000,000 (chart 4). Does a connection

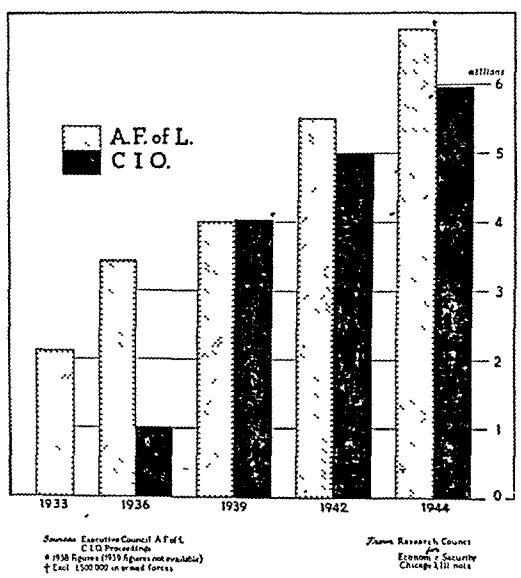

Chart 4.—Membership of labor unions in the United States, 1933 1944.

exist between the growth of organized labor and the increasing demand for compulsory health insurance? If the idea seems farfetched, look at the development of the demand in several states.

In California the period of 1912 to 1920 was marked by economic instability. Soon after the turn of the century, labor interests became increasingly active. From 1901 to 1907, and again from 1909 to 1911, the Union Labor Party elected the mayor of San Francisco. Socialists and Communists began to enter the labor unions in force, and the leadership inclined to be radical. The Industrial Workers of the World gained in power and influence. Labor union membership amounted to 45,000 in 1910 and rose to 69,000 in 1915 and to 104,200 in 1920. Beginning with the Initiative and Referendum Act in 1911, social legislation continued to increase, with four major social welfare acts adopted in 1913.

The depression, beginning in 1929, struck California severely. The index of employment declined from 100 in 1929 to 75 in 1931 and to 62 in 1934. A considerable burden was added to the state economy by the large migration of victims of the depression from other

states. Between 1932 and 1936, it is estimated, no fewer than 300,000 migrants entered the state.

Labor union membership, which at the beginning of the depression had difficulty holding its own, increased rapidly from 1935 on. In that year it amounted to 102,000 but by 1940 had climbed to 650,000. The period of depression was characterized by the severity of organized strikes. The Cannery and Industrial Workers Union struck in 1933, and the following year the International Longshoremen's Union called a strike in San Francisco with 25,000 workers involved. Socialist and Communist influence was strongly felt, especially in the Democratic party, which, under the leadership of Governor Olson, sponsored the compulsory health insurance proposals of 1939. Between 1929 and 1936 four important social welfare acts were passed by the state legislature. One group of which all political leaders must take account in California is that of the aged, who during the last twenty years or more have proved a most powerful source of political activity.

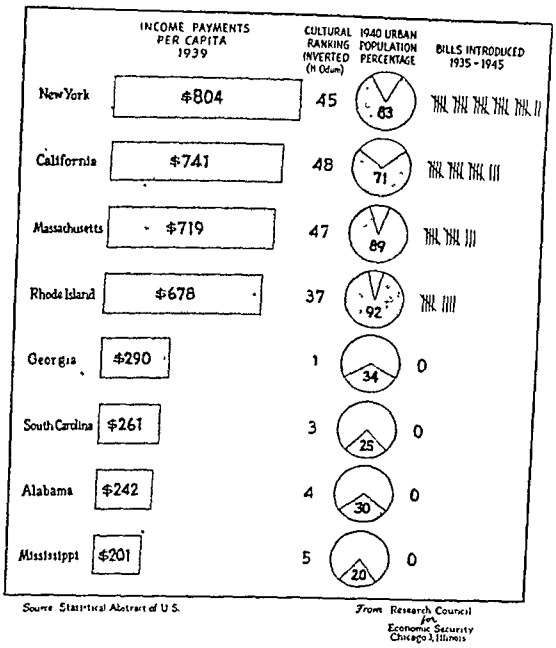

Chart 5.—Economic and social progress versus the demand for health insurance.

All these groups, the unions, the aged, the Socialists, the Communists, combined to create, between 1933 and 1938, some of the most flamboyant and utopian proposals that have ever appeared on the American scene. In 1933 the Utopian Society advocated a perfect society to the slogan of "A New Economy of Abundance." In 1933-1934 cooperative groups and societies expanded considerably, culminating in the barter scheme of "Tradex." Technocracy in 1934 came out with a highly artificial scheme of technology and finance. Between 1934 and 1936 the E. P. I. C. scheme advocating state socialism flourished, nominating a candidate for governor. Launched in 1934, the Townsend movement proposed a monthly payment to the aged. The "Ham-and-Eggs" movement proposed a weekly bonus, polling 1,000,000 votes in the 1938 election.

New York State has seen perhaps more attempts to introduce compulsory health insurance than any other state. During the last decade twenty-seven bills have been presented in the state legislature. The location of the national headquarters of many reform organizations in New York City has been probably responsible for this activity. But the strongest proponent has been the New York State Federation of Labor. In 1935 it had 850,000 members—exclusive of the four railway brotherhoods—organized in eight hundred unions, city labor bodies and district trade councils. About 55 per cent of the membership is in New York City. The State Federation maintains a permanent legislative committee, which works with about twenty labor newspapers throughout the state. In recent years the C. I. O. has entered the scene with equally vigorous activity.

In contrast to California and New York, Mississippi has seen little demand for compulsory health insurance in spite of the obvious need for better medical care. No bills calling for state health insurance have appeared in the legislature, nor has any organized group advocated such action. Standard social legislation such as has appeared in other states has not been enacted in Mississippi. If there had been any organized groups or labor unions in the state there probably would have been more legislative activity favoring compulsory health insurance. The absence of labor or group action is due to the weakness of organized labor. There are only a few local unions. The American Federation of Labor has no state branch.

As may be seen from comparison between the highly vocal demand for compulsory health insurance in California and New York, on the one side, and the absence of any organized demand in Mississippi, on the other (chart 5), certain conditions help or hinder the development of such a demand. These conditions make themselves felt regardless of prosperity or depression, being a result of the state's economic and social development. In Mississippi, for instance, a predominantly rural state with a large Negro population, conditions do not favor the organization of groups or unions, even with the stimulus that comes from a period of depression. In California and New York, however, conditions always favor collective action, even in times of prosperity.

FACTORS CONDUCIVE TO DEMAND

California's population is 71 per cent urban, the state having seven cities with a prewar population of 100,000 or over. This makes for congregation and collective action. With its nearly 300,000 wage earners in manufacturing industries (1939) it ranks among the ten leading states. This facilitates labor organization. In addition, since 1940 about 1,300,000 newcomers have settled in California, working mostly in shipyards, aircraft factories and other industries.

With a per capita income of $741 in 1939, against a national average of $539, California is one of the wealthiest states in the Union. This makes for extensive development of modern medical service and equipment and spurs the appetite for even better facilities. Finally, California's population is marked by a high degree of mobility caused by five principal factors: extensive foreign trade, large tourist movement, influx of migratory workers, the climate attracting many older people and the lure of Hollywood. This mobility makes for novel, sometimes startling, economic ideas and social experimentation.

New York has likewise an abundance of factors conducive to the demand for compulsory health insurance. In view of the fact that New York has by far the largest number of manufacturing establishments and of wage

earners, as well as the highest amount of wages and products, it is no surprise that labor organization is perhaps more highly developed in this than in any other state. In urban development New York ranks high, having twelve cities with over 100,000 population (1940). New York City, especially, probably yields more instances of collective action and pressure than any other city.

In per capita wealth New York outranks every other state with the exception of New Jersey. Accordingly, medical services and facilities have been developed to the highest degree and in turn have provoked the desire for still further improvements. Finally, the state has the most cosmopolitan population of any state. Before the war less than 80 per cent of its population was native born against more than 90 per cent for the country as a whole. The substantial share of foreign population, apart from the large proportion of first generation Americans, is undoubtedly responsible for the introduction of many social ideas partly copied from foreign countries. *Mississippi is the antithesis for both California and New York.* In industrial development it ranks among the lowest of all the states. There are virtually no large cities; hence there is little opportunity for mass action. In per capita income it stands at the very bottom. Therefore the development of medical facilities compares unfavorably with that of other states and is largely dependent on out of state help. Owing to the absence of industrial wealth and opportunity and with a population half white, half Negro, few foreign ideas enter the state, and those that do are instantly discouraged.

CONCLUSIONS

The demand for compulsory health insurance, it may be concluded, is promoted most powerfully by organized collective action, especially by organized labor. However, the opportunity for such action is not always present. It is easier to organize in depression than in prosperity, easier in industrial than in agricultural states, easier in large cities than in small towns, easier in areas where medical service and facilities are well organized.

We are then in a position to summarize as follows:

The most powerful single force responsible for the origin of the demand for compulsory health insurance is organized labor.

The time most conducive for this demand is a period of depression.

The place most conducive for formulation and pressing of such demand is the large city.

Apparently, the opportunity to organize the demand is more important than the prevalence of the need for medical care. The evidence points to the probability that, contrary to popular belief, the legislative proposals for compulsory health insurance are based not so much on social needs as on political interests, and that the ability on the part of labor to organize and press the demand, rather than the concern about the state of health, is the primary consideration.

Organized labor is strongest in the most highly industrialized and urbanized sections of the country. It is only natural that labor-promoted plans for compulsory health insurance are designed chiefly in the interests of industrial labor and are modeled to fit the conditions prevailing in highly developed areas. But these conditions are not typical of the country at large, nor are they the major part of our national health problem. Therefore it may be said that such plans hardly promise an adequate solution of that problem, which is made up of many different factors apart from those that characterize conditions in the large cities.

Illness apparently is not chiefly responsible for the demand for compulsory health insurance. If it were, recommendations would start in the medically least progressive states. However, they originate at the opposite end of the scale, where medical care and social services are most highly developed. The proposed recommendations do not and apparently are not designed primarily to solve the health problems in rural areas, economically underdeveloped regions and among underprivileged groups.

There are three principal aspects of our national health problem:

(*a*) The need for medical care and hospital facilities where none now exist. This is largely a problem of constructing hospitals and of organizing medical services, both of which could probably be realized more effectively on a state or local than on a federal scale.

(*b*) *The need for better sanitation and hygiene.* This is chiefly a public health project and one for state and local government to put into operation, probably with the help of federal subsidies.

(*c*) The need for economic development which would enable more remunerative employment for the people. This applies especially to predominantly agricultural states such as Mississippi, Alabama, Arkansas, Georgia and the Carolinas. It would mean crop rotation, improved irrigation, more industrialization, better education, vocational training and the development of foreign trade.

How, then, can the federal government cooperate in improving, directly or indirectly, the health of the people? The health problems of Mississippi are similar to those of Arkansas, Missouri, Kentucky, Tennessee, Georgia and Alabama. They constitute a regional rather than a national problem. Therefore, participation on the part of the federal government may well be confined to financial subsidies, of which Mississippi has been a recipient in the past, and to the construction of hospitals, clinics and other medical facilities. The important difference between such an arrangement and a federal system of compulsory medical care and hospitalization lies in the fact that the all important administration of these services would not be monopolized in the hands of the federal government but could be assumed by private enterprise and, if needed, by local government units. A voluntary setup, while making full use of federal resources, would neither interfere with the health and medical conditions in other states nor attempt to impose on a state like Mississippi provisions and benefits adapted to urbanized and industrialized regions and not designed for the special conditions of the agricultural South.

State and local authorities can give full consideration to local requirements, whereas the federal government cannot. Moreover, the authority of the state would be limited as against the practically unlimited power of government authority if administration of social services was concentrated in federal hands. Finally, a compulsory system of health insurance would be kept within the limited resources of the state, with regard both to cost and to political exploitation, whereas it would be virtually without limitation on a federal basis. If necessary, the restricted financial resources of the state could be supplemented by federal aid.

Previous pages have indicated the growth in volume and extent of protection provided by private

enterprise. No doubt this could be further promoted by common and concerted action among the various carriers—insurance companies, medical organizations, nonprofit hospital plans, industrial societies and mutual benefit associations. There is little reason to doubt that an agreement on collective action would go far in making possible extended protection against sickness at substantially lower cost than is possible under separate plans.

All these considerations emphasize the need for careful deliberation with regard to current or contemplated proposals for compulsory health insurance. Another important factor is the lack of factual comprehensive information. In view of the absence of specific data as to the exact need for medical care, any legislative proposal could hardly be based on anything more substantial than general ideas obtained from overall estimates. As a result, benefits are not determined on local requirements. The exact cost is not known. The rate of taxation cannot be fixed with any degree of accuracy. A reliable and complete survey of the health problem of the states and of the nation has never been made. Until it is made, and until more information is available, not only as to the cost of compulsory systems but of the effect on such widely divergent factors as government, taxes, enterprise and human nature, care should be taken by the citizen and his legal representatives to weigh carefully the pros and cons before they decide what they want in the way of health insurance for themselves, for their children, for their state and for their nation.

176 West Adams Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

"AN APPRECIATION"

The Council on Physical Medicine desires to take this opportunity to express its feelings of gratitude and appreciation for the services of the following consultants, whose assistance in carrying out the work of the Council has been given so freely during the past year: Drs. Milton B. Cohen, Clement J. De Bere, Hart Fisher, K. G. Hansson, John S. Hibben, Alexander Hollaender, Arno B. Luckhardt, S. L. Osborne, Perry Pepper, Scott M. Reger, Bernard D. Ross, Henry Schwerma, Ralph Waters and W. F. Wells.

Audiometers and Hearing Aids.—Drs. Gordon Berry, E. P. Fowler, W. E. Grove, Isaac Jones, Dean Lierle, Moses Lurie, Douglas Macfarlan, C. Stewart Nash, Horace Newhart, Paul Sabine and B. R. Shurly.

Educational Work.—Drs. Frances Baker, Robert L. Bennett, Benjamin Boynton, Earl C. Elkins, F. H. Ewerhardt, Richard Kovacs, Fred B. Moor, W. H. Northway, William Schmidt and Walter M. Solomon (in service).

Ophthalmic Devices.—Drs. Thomas D. Allen, Charles A. Bahn, S. Judd Beach, Conrad Berens, Frederick Carl Cordes, Alfred Cowan, L. T. Post and Avery C. Prangen.

Artificial Limbs.—Drs. Harry E. Mock, S. Perry Rogers, Paul Steele and Philip Wilson; Messrs. McCarthy Hanger Sr., W. E. Isle, J. B. Korrady, Joseph Spievak and David E. Stolpe.

Respirators.—Drs. Walter B. Cannon, Edward L. Compere, Charles McKhann and James Wilson.

Electrocardiographs.—Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, William D. Stroud, Carl J. Wiggers and Frank H. Wilson.

Roentgen Therapy.—Drs. William Edward Chamberlain, Arthur Carlisle Christie, Edwin Charles Ernst, Gioacchino Failla, Fred Murchison Hodges, John Thomas Murphy, deceased, Robert Reid Newell, Eugene Percival Pendergrass, Ursus Victor Portmann, Lauriston S. Taylor and J. L. Weatherwax.

Contraceptive Devices.—Drs. Nicholson J. Eastman, William W. Greulich, Lieut. Comdr. Joseph Hughes, Dr. A. C. Ivy, Prof. Walter J. Meek and Dr. Ephraim Shorr.

Occupational Therapy.—Drs. Raymond Allen, Winfred Overholser, Col. Howard A. Rusk, Drs. William Stroud and Francis Trudeau.

YOUNG RECTAL DILATORS NOT ACCEPTABLE

Manufacturer: F. E. Young & Company, Chicago.

The Young Rectal Dilators consist of plugs of graded sizes designed to stretch the external sphincter muscle of the anus. They are made of a plastic material.

The Dilators are intended to be used by the patient following the instruction of a physician. The firm claims the Dilators are useful in the treatment of chronic constipation and that they are sold only on a physician's prescription.

The firm submitted a list of physicians who have had experience with the Dilators and also eighteen letters from physicians who have prescribed the device. The evidence presented in these letters is merely a description of the writer's experience and is devoid of scientifically controlled data.

The Council's investigator reported that the Young Rectal Dilators were dangerous and that they are likely to cause harmful effects when used by the patient. Examination of the information which the firm submitted does not reveal acceptable scientific evidence to substantiate their value. The Council voted, therefore, not to accept the Young Rectal Dilators, because of the lack of adequate evidence of their therapeutic efficacy.

PARAVOX MODEL VV2 RADIO TUBE HEARING AID ACCEPTABLE

Manufacturer: Paraphone Hearing Aid Company, Inc., 2056 East Fourth Street, Cleveland 15.

The Paravox Model VV2 is a two tube instrument with transmitter, amplifier and batteries in one case. A single cord attaches to the case, connected to which is a crystal receiver.

Physical dimensions:

Case: 5 1/16 by 2 5/16 by 1 1/8 inches.

Receiver: Either 1 inch diameter or 3/4 inch diameter crystal.

Weight: Case (containing batteries, transmitter and amplifier) 11 ounces.

Current consumption:

A battery (1½ volts) 68 milliamperes.

B battery (30 volts) 0.5 milliampere.

Battery drain is independent of volume control setting.

Acoustical gain for speech: With 1 inch diameter crystal receiver and full volume, 31 decibels. This gain represents the average gain for 3 persons, each of whom had losses of from 40 to 50 decibels for air conduction from 256 to 2,048 cycles. These persons perceived speech through a high quality sound system at an average level of 31 decibels less intensity with the hearing aid than without it.

Acoustical gain for pure tones:

Frequency	250	500	1,000	2,000	3,000	4,000	5,0
Full gain in decibels (large receiver)	16	30	42	43	34	26	3

These measurements were obtained with an artificial ear. The hearing aid was mounted on a body baffle. The foregoing values do not indicate absolute sound pressure values but indicate the amplification efficiency of the instrument at the frequency levels shown.

Physical and mechanical features: The amplifier and batteries are contained in a single case of black enameled metal. The combined volume and "on-off" switch consists of a knurled disk at the top of the case. The case is slightly larger and heavier than the conventional tube hearing aid transmitter case, since it also contains the batteries. The total weight is less than that of the conventional instrument, which has separate cases for the transmitter and batteries.

Performance: This instrument operates in an entirely satisfactory manner. There is a minimum of inherent amplifier, case and cord noise.

Recommendation: The Council on Physical Medicine voted to include the Paravox Model VV2 Radio Tube Hearing Aid in its list of accepted devices.

PARAVOX MODEL VV3 RADIO TUBE HEARING AID ACCEPTABLE

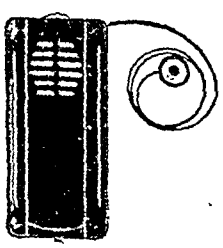
Manufacturer: Paraphone Hearing Aid Company, Inc., 2056 East Fourth Street, Cleveland 15.

The Paravox Model VV3 is a three tube instrument with transmitter, amplifier and batteries in one case. A single cord attaches to the case, connecting to a crystal receiver.

Physical dimensions:

Case: 5 1/16 by 2 5/16 by 1 1/8 inches.
Receiver: Either 1 inch diameter or 3/4 inch diameter crystal.
Weight: Case (containing batteries, transmitter and amplifier) 11 ounces.

Current consumption:



A battery (1½ volts) 65 milliamperes.
B battery (30 volts) 0.6 milliampere.
Battery drain is independent of volume control setting.

Acoustical gain for speech: With 1 inch diameter crystal receiver and full volume, 44 decibels. This gain represents the average gain for 3 persons, each of whom had losses of from 40 to 50 decibels for air conduction from 256 to 2,048 cycles. These persons perceived speech through a high quality sound system at an average level of 44 decibels less intensity with hearing aid than without it.

Acoustical gain for pure tones:

Frequency.....	250	500	1,000	2,000	3.000	4,000	5,000	6,000
Full gain in decibels (large receiver)....	29	46	51	55	46	45	29	11

These measurements were obtained with an artificial ear. The instrument was mounted on a body baffle. The foregoing values do not indicate absolute sound pressure values but indicate the amplification efficacy of the instrument at the frequency levels shown.

Paravox Model VV3 Hearing Aid

Physical and mechanical features: The amplifier and batteries are contained in a single metal case, finished with smooth black enamel. The combined volume control and "on-off" switch consists of a knurled disk at the top of the case. The case is slightly larger and heavier than the conventional tube hearing aid transmitter case, since it also contains the batteries. The total weight is less than that of the conventional instrument, which has separate cases for the transmitter and batteries. The 1½ volt A battery (small or size C flashlight battery) and the 30 volt B battery (special small size hearing aid battery) cannot give as many hours of service as can be anticipated from the larger size batteries usually used with three tube instruments.

Performance: The Paravox Model VV3 operates in an entirely satisfactory manner. There is a minimum of inherent amplifier, case and cord noise.

Recommendation: The Council on Physical Medicine voted to include the Paravox Model VV3 Radio Tube Hearing Aid in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES-1945 OUT IN AUGUST

Considerable delay has been experienced in preparing the bound volume of New and Nonofficial Remedies-1945. The printing of the final forms is now in progress, and, when the binders have finished, the book will be available, it is hoped, some time in August. Difficulty in procuring paper, scarcity of personnel and other causes have contributed to this unavoidable delay. It is especially regretted that these circumstances have postponed the distribution of the paper bound copies which are given each year to one class of each accredited medical school.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its actions will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

SCARLET FEVER STREPTOCOCCUS TOXIN, TANNIC ACID PRECIPITATED.—A sterile buffered solution containing in suspension a tannic acid precipitate of scarlet fever toxin and 0.4 per cent phenol as a preservative.

Actions and Uses.—This tannic acid precipitated toxin is claimed to permit slower absorption and a prolonged antigenic stimulus which permits a reduction in the amount of toxin and size of dose as compared with former methods of immunization.

Dosage.—Children receive three intracutaneous injections of 0.1 cc. (dose 1, 750 STD/0.1 cc.; dose 2, 3,000 STD/0.1 cc.; dose 3, 10,000 STD/0.1 cc.) at two week intervals. Some may need a supplemental dose after a four week interval.

Adults may receive 500, 2,000, 6,000 and 10,000 STD at two week intervals. Each vial should be well shaken before use. The toxin should not be used beyond expiration date on label or if it does not resuspend completely on shaking.

Preparation.—Scarlet fever toxin is prepared from cultures of hemolytic streptococcus, N Y-5 (Dochez) strain, and treated with ammonium sulfate. The ammonium sulfate precipitate is dissolved in sterile saline solution, buffered at p_H 6.6 and preserved with phenol. Samples of the toxin which meet the requirements of the National Institute of Health are further treated by the addition of sterile diluent and 0.5 per cent solution of tannic acid.

The tannic acid precipitated toxin is washed free of tannic acid and suspended in buffered saline solution containing 1 per cent acacia. The suspension is assayed for skin test dose potency and diluted suitably for market packaging. The finished product is preserved with 0.4 per cent phenol and complies with the requirements of the National Institute of Health of the United States Public Health Service.

WYETH INC., PHILADELPHIA

Scarlet Fever Streptococcus Toxin for Immunization, Tannic Acid Precipitated: 0.5 cc. single immunization vials and 2 cc. 10 immunization vials packaged in units of three vials (children) contains respectively in each 0.1 cc. 750, 3,000 and 10,000 skin test doses; and in units of four vials (adult) containing in each 0.1 cc. 500, 2,000, 6,000 and 10,000 skin test doses. Also 0.5 cc. single and 2 cc. ten dose vials containing a supplementary dose for children and adults, representing in each 0.1 cc. 10,000 skin test doses. Preserved with phenol 0.4 per cent.

COD LIVER OIL WITH VIOSTEROL (See New and Nonofficial Remedies, 1944, p. 630).

The following additional dosage form has been accepted:

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Cod Liver Oil with Viosterol: 473 cc. Each 1 Gm. has a potency of not less than 1,800 U. S. P. units of vitamin A and of not less than 400 U. S. P. units of vitamin D.

PERCOMORPH LIVER OIL (See New and Nonofficial Remedies, 1944, p. 636).

The following additional dosage form has been accepted:

MEAD JOHNSON & COMPANY, EVANSVILLE, IND.

Capsules Oleum Percomorphum with Other Fish Liver Oils and Viosterol: 83 mg.

SATURDAY, JULY 21, 1945

THE CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

On June 22 the Council on Medical Service and Public Relations of the American Medical Association, meeting with the Board of Trustees, developed a program for the extension of health and medical care in the United States, published elsewhere in this issue. This program is so direct in its statements of objectives to be achieved that it requires little interpretation. By it the Association supports improvement in nutrition, housing and living conditions that are fundamental to good health. Again it places the American Medical Association behind the extension of qualified public health and preventive medical service. The program recognizes that plans for insurance against the costs of hospitalization on a voluntary basis have now been sufficiently developed to warrant support, although some controversial questions have not yet been satisfactorily settled. The care of the indigent, for which there are no suitable provisions under existing or proposed national or other compulsory sickness insurance plans, may by new technics be incorporated into voluntary sickness insurance plans.

Fundamental to a scientific plan for meeting needs for medical care is the scientific survey which determines the existence and scope of such needs. This fact is recognized in the proposals that surveys be made to determine these needs and that federal aid be given where needs are demonstrated, with the understanding that administration and control will be under local auspices. Scientific also is the proposal for continuous surveys of all plans leading toward their extension and improvement as new needs are shown.

The final measures in this program relate to problems associated with the war and the situations created by military service. More than 60,000 physicians have been involved in military and other government services, while less than 90,000 physicians have tried to meet the needs of the civilian population. On these civilian physicians has rested a great burden. Every one now agrees that discharge of physicians from the armed services as rapidly as possible is necessary for the maintenance of medical care of the quality that has prevailed in this country. Associated with such discharge must come relocation and redistribution of physicians, since the needs of various communities have been modified by conditions related to the war. Certainly the desires of the men who have given so greatly of themselves both to the men in the armed services and to the civilian population during the war years merit consideration. It would be unfair to force revolutionary changes in medical practice on these physicians while they are away from their homes and have not had opportunity to voice their opinions. This applies equally to the 12,000,000 men and women who have fought to preserve the American form of government.

The needs of medical education have been told repeatedly and are again emphasized in this constructive program. Unless plans provide for a sufficient number of young men and women in the premedical curriculum, the nation will face a desperate shortage of physicians in coming years, a shortage made more acute by increased demands of the armed forces and of various government agencies for trained physicians. The needs of the Veterans Administration for physicians will far exceed any demands ever made previously by that agency.

THE RELEASE OF MEDICAL OFFICERS FROM THE ARMED FORCES

Almost simultaneously with the coming of V-E day, physicians, as well as most other members of the armed forces, began to look forward to the day of their release from military service. The unrest inevitably associated with uncertainty as to the future was, of course, heightened by the sudden cessation of routine medical activities, so that many a physician chafed over being held in service without work to do. The dissatisfaction was further heightened when announcement of a system of release of men on a point system was made, yet without any statement as to the technic by which officers would be discharged from the service. More recently announcement has been made from the Office of the Surgeon General that from 2,000 to 3,000 physicians might be released by January 1946 or indeed that as many as 7,000 might be released by May 1946.

On July 11 Senator Johnson of Colorado accused the Army of taking a "leisurely attitude" toward release of physicians who are urgently needed for the civilian population. Other members of the Military Affairs Subcommittee also urged the Army to speed the release of physicians. Some dissatisfaction arises, as was indicated in a letter from five military medical officers published in The Journal last week, over the concept that the Army is not taking in any new young men but apparently will hold on as long as possible to those it already has. To these claims and charges the Army Medical Department replies that the European war

may be ended but there still remain the problems associated with the armies of occupation, the intensified war with Japan in the Pacific, the requirement that the sick and disabled be kept in the Army until they have reached maximum recovery, and medical routines associated with the discharge of men from the armed forces.

In a consideration of the questions associated with the discharge of British medical officers, the London *Lancet* points out that it was possible to invade France with a cover of less than 5 hospital beds for each hundred men but that it is necessary in the Far East, with "its long lines of communication, its abominable climates and its special risks from endemic and epidemic disease" to furnish 10 beds for every hundred troops and physicians and medical personnel to staff them.

The suggestion that young men who have recently completed internships and residencies be taken into the military service to replace older physicians now in the service is not wholly sound. This would not provide the Army with the highly specialized services that can be provided only by older men. The necessary peripheral nerve surgery, vascular surgery, plastic surgery and highly specialized diagnostic and therapeutic skills of internal medicine, psychiatry, dermatology and ophthalmology, for example, will not be made available by taking new young men into the service.

The physicians of the armed forces may be assured that every agency of the American Medical Association that can possibly be helpful is seriously engaged in this problem. The Committee on Postwar Medical Service, the Board of Trustees and all of the facilities of the headquarters office are doing their utmost to aid officers in the Office of the Surgeons General in solving problems related to the discharge of medical officers. Years were required for mobilizing the armies and medical services of our nation; release cannot be accomplished overnight.

OLEOMARGARINE

With the advent of war there has been a considerable decrease in edible fats available for civilian consumption. As a means for increasing the supply of solid edible fat to replace the decreasing amount of butter available for nonmilitary populations, margarine has been increasingly emphasized. Aside from the fact that this food has been fortified to the extent of 9,000 international units of vitamin A per pound to compensate for its lack of this vitamin, much discussion has concerned the nutritional value of fortified margarine as compared with butter fat. Various economic interests have been injected into this discussion, but only recently has objective evidence on the nutritional value of this fat been available.

Deuel and his associates [1] found that growing rats could use either butter fat, various vegetable fats or margarine with equal ease. The animals grew equally well, as shown by increase in weight and increase in bone length, whether their dietary fat consisted of butter fat or of margarine. In addition, Deuel [2] made careful analyses of the rats maintained on diets containing the various fats and found that there was no difference in the protein, lipid, ash or water content of the tissues of the animals. Then Elvehjem and his associates [3] showed that margarines permitted satisfactory growth in rats when the carbohydrate of the diet was glucose, sucrose, starch, dextrin or a mixture of them, whereas, when lactose was the sole carbohydrate of the diet, the rats grew better when butter or lard rather than oleomargarine was the fat used.

Deuel and his associates [4] studied the effect of different fats on fertility and lactation, since under these circumstances the dietary requirements constitute a more stringent test of nutritional adequacy than does growth. Difference was not found in the fertility of male or female rats on diets which contained various fats, irrespective of whether the fat was butter, margarine, corn, olive, peanut or soybean oils, provided the diets were supplemented with the proper fat soluble vitamins. All the diets produced young of equal weight at weaning, showing that they were equally efficacious in promoting lactation. These results would indicate that butter per se is not required for the growth or lactation of the rat. Perhaps then nutritional deficiency might occur in subsequent generations of animals whose diet was deficient in butter fat; a study [5] was carried out in which ten generations of rats were maintained on a diet containing margarine fortified with vitamin A in place of butter fat. Vegetable fats such as those used in margarine, the evidence proved, can serve adequately in place of butter fat in regard to growth, reproduction and lactation on a diet which would be otherwise nutritionally satisfactory.

The experimentalists in nutrition have shown that margarine may be substituted for butter fat with impunity in regard to growth, reproduction and lactation, provided the diet is nutritionally adequate. Of all the fat soluble vitamins, margarine is deficient in vitamin A, but this deficiency is made up by the fortification of the product with added vitamin A. This is a common procedure and most products on the market today are fortified in this way. The possibility of using margarine as a low cost fat may be of considerable importance in the feeding of the war seared population of Europe; it may also be used with safety in this country when a less costly edible fat is needed.

Current Comment

INFORMATION BULLETIN FOR MEDICAL OFFICERS READY

Information of special value to medical officers about to reenter civilian life has been published at frequent intervals in THE JOURNAL. Various agencies of the American Medical Association, including the Committee on Postwar Medical Service, the Bureau of Information, the Council on Medical Education and Hospitals and the Bureau of Legal Medicine and Legislation, have taken part in gathering this information. In order to make this material more readily available, the Bureau of Information has prepared a pamphlet entitled "Information Bulletin for Medical Officers," which contains a digest of the G. I. Bill of Rights, educational facilities in civilian institutions, aids in establishing a practice, licensure and reciprocity data and certification by specialty boards. This pamphlet is now ready for medical officers and through the courtesy of the Surgeons General of the Army, Navy and Public Health Service will be sent to all physicians in those services. A brief digest of this material cannot answer all the questions which may arise. It is indicated in the pamphlet, however, how additional information on specific problems may be obtained.

THE FACTORS UNDERLYING THE DEMAND FOR COMPULSORY SICKNESS INSURANCE

The article by Strow and Hirschfeld in this issue of THE JOURNAL is offered as a report of a scientific investigation into the forces now promoting the mechanism for medical service incorporated in the Wagner-Murray-Dingell bill. The analysis reveals that legislative proposals for compulsory health insurance are not based on actual investigation of needs; neither are they apparently founded on anything resembling exact measurement of the extent of illness and failure to receive medical care. Strow and Hirschfeld offer proof that the demand for compulsory sickness insurance arises in those sections of the country where medical care and social services are most highly developed and that the demand is associated with the activities of highly organized labor groups. The demand is urban rather than rural. This investigation shows further that the chief problems in providing adequate distribution of medical service and facilities for health is the construction of new hospitals, the improvement of sanitation and hygiene, the improvement of economic conditions and the organization of medical services around medical institutions. This scientific report coordinates well with the program for extension of medical services developed through the Council on Medical Service and Public Relations and the Board of Trustees of the American Medical Association, also published in this issue of THE JOURNAL. The report by Strow and Hirschfeld is not opposed to organized labor; rather it is offered specifically to organized labor for study so that cooperation may be secured in extending to the worker, to the farmer and to people generally the most that American medicine can give under a democratic system of government. Compulsory sickness insurance leads to regimentation and totalitarianism. The continued evolution of plans for medical care with the acceleration that has been evident in recent years will yield technics for providing medical service adapted to the American way of life.

PUBLICITY FROM THE COMMITTEE OF PHYSICIANS

The so-called Committee of Physicians for the Improvement of Medical Care, Inc., has been sending out bulletins again. Apparently little, if any, attention is given to them, since they receive little if any comment in either medical or lay periodicals. Many, if not most, of the members of this committee are full time teachers in our medical schools. The chief concern of Statement No. 15 seems to be the effect of proposed legislation on such teachers. One absolute falsehood demands correction. The statement says "Since the American Medical Association is uncompromising in its insistence upon fee-for-service payment, this system would undoubtedly be elected by 'the majority of the general medical practitioners.'" Even casual observation or reading would reveal that this statement is not true. The statement expresses great fear that the so-called teaching hospitals associated with medical schools might be forced under one clause of the Wagner-Murray-Dingell bill to become open hospitals. This, they say, "would destroy the present organization of clinical faculties and the possibility of controlling the quality of medical care." The final demand in their statement is "special provisions for the protection of educational institutions." The narrowness of the point of view of this group can now be clearly understood by the medical profession. The names of the committee are here repeated as published in Statement No. 15:

Channing Frothingham, chairman
Milton C. Winternitz and Carl Binger, vice chairmen
Russell L. Cecil, honorary chairman
John P. Peters, secretary and treasurer

Alf S. Alving	Harry S. Mackler
Bertram Bernheim	Irvine McQuarrie
Ernst P. Boas	J. H. Means
Samuel Bradbury	T. Grier Miller
Allan M. Butler	George R. Minot
Alexander M. Burgess	Fred D. Mott
Hugh Cabot	Robert B. Osgood
Louis Casamajor	Walter L. Palmer
Thomas B. Cooley	H. B. Richardson

One wonders how many of them read or understood the purport of Dr. John Peters' latest revelation.

CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

AMERICAN MEDICAL ASSOCIATION

This platform was adopted by the Council on Medical Service and Public Relations and the Board of Trustees of the American Medical Association on June 22, 1945.

Preamble

The physicians of the United States are interested in extending to all people in all communities the best possible medical care. The Constitution of the United States, the Bill of Rights and the "American Way of Life" are diametrically opposed to regimentation or any form of totalitarianism. According to available evidence in surveys, most of the American people are not interested in testing in the United States experiments in medical care which have already failed in regimented countries.

The physicians of the United States, through the American Medical Association, have stressed repeatedly the necessity for extending to all corners of this great country the availability of aids for diagnosis and treatment, so that dependency will be minimized and independence will be stimulated. American private enterprise has won and is winning the greatest war in the world's history. Private enterprise and initiative manifested through research may conquer cancer, arthritis and other as yet unconquered scourges of humankind. Science, as history well demonstrates, prospers best when free and unshackled.

Program

The physicians represented by the American Medical Association propose the following constructive program for the extension of improved health and medical care to all the people:

1. Sustained production leading to better living conditions with improved housing, nutrition and sanitation which are fundamental to good health; we support progressive action toward achieving these objectives.

2. An extended program of disease prevention with the development or extension of organizations for public health service so that every part of our country will have such service, as rapidly as adequate personnel can be trained.

3. Increased hospitalization insurance on a voluntary basis.

4. The development in or extension to all localities of voluntary sickness insurance plans and provision for the extension of these plans to the needy under the principles already established by the American Medical Association.

5. The provision of hospitalization and medical care to the indigent by local authorities under voluntary hospital and sickness insurance plans.

6. A survey of each state by qualified individuals and agencies to establish the need for additional medical care.

7. Federal aid to states where definite need is demonstrated, to be administered by the proper local agencies of the states involved with the help and advice of the medical profession.

8. Extension of information on these plans to all the people with recognition that such voluntary programs need not involve increased taxation.

9. A continuous survey of all voluntary plans for hospitalization and illness to determine their adequacy in meeting needs and maintaining continuous improvement in quality of medical service.

10. Discharge of physicians from the armed services as rapidly as is consistent with the war effort in order to facilitate redistribution and relocation of physicians in areas needing physicians.

11. Increased availability of medical education to young men and women to provide a greater number of physicians for rural areas.

12. Postponement of consideration of revolutionary changes while 60,000 medical men are in the service voluntarily and while 12,000,000 men and women are in uniform to preserve the American democratic system of government.

13. Adoption of federal legislation to provide for adjustments in draft regulation which will permit students to prepare for and continue the study of medicine.

14. Study of postwar medical personnel requirements with special reference to the needs of the veterans' hospitals, the regular army, navy and United States Public Health Service.

MEDICINE AND THE WAR

THE SUPPLY OF MEDICAL STUDENTS AND PHYSICIANS

Memorandum presented on June 4, 1945 to President Harry S. Truman by a special committee of the Committee on Postwar Medical Service consisting of Evarts Graham, M.D., St. Louis; Victor Johnson, M.D., Chicago; Harvey Stone, M.D., Baltimore, and Fred C. Zapffe, M.D., Chicago.

Whatever measures may be taken in the near future for the improvement of the health of this nation, including the construction of additional hospital facilities and the extension of various plans of prepayment insurance against sickness, it would seem to be axiomatic that physicians must be provided in adequate numbers if these measures are to succeed. Yet we are now failing to provide for the training of enough physicians to meet the demands for doctors which we know will increase after the war.

At that time we shall need about 30,000 more physicians than before the war, primarily because of the requirements of the Veterans Administration (about 15,000) but also because of the needs of the peacetime Navy (about 5,000) and the Army plus possibly a compulsory universal military training program (about 10,000). This estimate disregards extra physicians required to provide replacements for casualties among medical officers, medical assistance to liberated countries and the more complete and extensive medical care demanded in this country.

Even if admissions, enrolments and graduations from our medical schools should continue at the present wartime levels, only about half of this need would be met, since 40,000 students will receive the M.D. degree in the period 1942 to 1948 and 24,000 physicians will have died during that time. Thus, under the most favorable conditions only about 16,000 additional physicians will be available after the war to do the work of 30,000.

In spite of this, freshmen enrolments in the medical schools of this country will be drastically reduced within the next year. In the past year virtually no able bodied males have been permitted to commence the two year course of college premedical studies because the Army and Navy have ceased assigning men to such studies and the Selective Service System has discontinued deferments of premedical students. In the past few years each freshman class of about 6,000 students included 4,000 to 5,000 able bodied men. These are no longer available under existing regulations.

From now until some time after the war, medical schools must enroll their freshmen from the following limited groups: women, physically disqualified males, men under or over the draft age and veterans. Relatively small numbers are available in these categories: medical schools annually receive applications from only 800 to 900 women and even fewer physically disqualified males; men under 18 or over the draft age can be disregarded, since there is only a handful of such students enrolled in medical studies. These three categories would scarcely supply 1,200 to 1,500 entering freshmen for the medical school classes of early 1946, even if all who applied to medical schools were admitted, with complete disregard for the qualifications of the applicants for the study and practice of medicine.

Major Gen. Lewis B. Hershey, the director of the Selective Service System, has stated that several hundred, or even a few thousand, acceptable medical applicants should surely be forthcoming from the hundreds of thousands of veterans being discharged from the armed forces. Checking on this statement indicates that it is a belief without foundation in fact. Eight large universities (California, Chicago, Illinois, Iowa, Michigan, Minnesota, Northwestern and Wisconsin), which normally supply 800 to 900 of the entering freshmen in our medical schools, now have enrolled just 42 veterans in premedical studies who will complete their preparation for entrance into medical school before 1947. Only 28 of these were considered probably acceptable as medical students and physicians. Generalizing from these data, it would seem that veterans may be expected to provide less than 4 per cent of the freshman class before 1947, totaling perhaps 200 to 300 students as compared with the total of 6,000 normally admitted.

Within the next year medical school freshmen admissions will be reduced by about 5,000 because of the existing policies and there will be an equal reduction in M.D. graduates three years hence. To write off 5,000 physicians is equivalent to depriving medical care from 100,000 hospitalized veterans, 1,000,000 soldiers or sailors or 4,000,000 civilians. Passage of even the best of the scores of medical care and hospitalization bills now pending in Congress and state legislatures would be ineffective and meaningless if we simultaneously prohibit the training of sufficient doctors.

This deficiency can be corrected under the present Selective Service Act as follows: Defer qualified men now in college premedical studies when they reach 18 and defer 8,000 selected high school graduates of this year to commence college studies in premedicine. From these, 4,500 should be earmarked for admission to specific medical schools a year later. Repetition of this procedure each year the war lasts would effect the training of enough doctors to care for the health of the people. Consideration might also be given to the assignment of a limited number of men now under arms back to premedical studies, provided they pursue such studies satisfactorily before induction, as far as this may be consistent with military necessity.

It is of basic importance to note that the restrictive regulations now in effect were promulgated a year ago. Since that time the war situation has radically changed. Even though we still have a tremendous task ahead, requiring the mobilization of all necessary resources, it remains true that the Selective Service System has recently announced a reduction in the rate of induction of men into the armed forces by 30,000 per month starting in July. It is not apparent that the deferment of a small percentage of this number of premedical students would in any way affect the military situation. On the other hand, it would help to insure adequate medical care of civilians, including veterans, after the war.

The acute need for an appropriate adjustment is underscored by the realization that the present policies will result in the same drastic reduction in medical school enrolments for each year that the Asiatic war lasts. It will even continue for a period after the peace, since premedical studies require two years before a student is ready to enter a medical school. The necessity for a continuous flow of students into and through our medical schools has been urged by the Surgeons General of the three armed services, by Mr. Paul McNutt of the War Manpower Commission, by Dr. Frank Lahey, chairman of the Directing Board of the Procurement and Assignment Service for Physicians, by every medical school in the country with a single exception and by virtually all medical educators and leaders in the medical profession. This conviction does not represent a special interest or problem of the medical profession or the medical schools. Actually, most medical schools would welcome an enforced period of relaxation from their arduous wartime program involving increased enrolments and acceleration of the training. The proposed adjustments are dictated only by the necessity for preserving the health of the nation.

ARMY

MEDICAL EQUIPMENT FOR SHIPMENT TO PACIFIC

Medical equipment being shipped to the Pacific is prepared at U. S. Army Medical Depot M-424, Honeybourne, England, the largest depot of its kind in England. Everything from delicate surgical instruments to x-ray machines is processed at this depot. Some 2,500 items are included in a so-called medical unit, which is sent as freight and does not accompany the hospital personnel. Certain surgical instruments require considerable time to prepare for shipment. A forceps, for example, gets a brisk cleaning in water, is dipped into carbon tetrachloride solution and is dried again. Then a technician, wearing rubber gloves, dips it again into a menthol solution to remove finger prints. After the forceps is dried it is covered with an oil preservative, then wrapped in an aluminum foil and finally hermetically sealed in cellophane. Thousands of individual surgical instruments require this treatment.

Major Charles A. Bohan, who is in charge of receiving and checking equipment at this depot, stated that bulky machines are torn down to save shipping space. If an item is damaged or rusted it is thrown into the salvage pile or "cannibalized" for good parts. Pacific bound hospitals will use only American equipment. British items turned in at the depot are declared surplus, with future disposition to be made by the Army's general purchasing agent.

57th STATION HOSPITAL

The 57th Station Hospital, located in Tunis, was recently awarded the Meritorious Service Unit Plaque for superior performance of duty during the period Jan. 1, 1944 to Nov. 1, 1944. The presentation of the plaque was the highlight of the army day celebration in Tunis, at which the American, English and French armies were well represented as well as members of the guard of the Bey of Tunisia.

The following medical corps officers are assigned to the 57th Station Hospital: Major Paul M. Fuller, commanding officer, Kalamazoo, Mich.; Capt. Alex E. Fairshter, ward officer, Philadelphia; Capt. George A. Greenberg, in charge of medical service, Somerville, N. J.; Capt. Joseph B. Johnston Jr., ward officer, Barium Springs, N. C.; Capt. Emory L. Mauritz, in charge of surgical service, Des Moines, Iowa, and Capt. Julius L. Samuels, eye, ear, nose and throat officer, Hollywood, Calif.

U. S. ARMY MEDICAL CORPS CONVALESCENT CAMP IN CHINA

A complete remedial therapy gymnasium has been constructed at the U. S. Army Medical Corps convalescent camp near Kunming, China, to hasten the recovery of American troops in the China theater following hospitalization for battle injuries, major operations, fractures and other casualties. Capt. Julius R. Pearson, Miami Beach, Fla., is the medical officer in charge. All the equipment at the camp has been built from salvaged materials. Parts of wrecked airplanes and jeeps, scrap metal and lumber, old steering wheels from trucks, tin cans, pipe and concrete are used in the construction of machines.

MERITORIOUS SERVICE UNIT PLAQUE

The Meritorious Service Unit Plaque was recently awarded to the 1798th Service Command Unit, Station Complement, Headquarters Detachment, Veterinary Section, Fort Des Moines, Iowa, for superior performance of duty in connection with food inspection activities throughout the state of Iowa during the last four years.

MEDICAL NUTRITION LABORATORY

The formal opening and dedication of the Army Service Forces Medical Nutrition Laboratory, Surgeon General's Office, U. S. Army, took place June 9 at the Chicago Quartermaster Depot. Major George H. Berryman, commanding officer of the Medical Nutrition Laboratory, presided.

DR. WILLARD O. THOMPSON AWARDED CERTIFICATE OF DISTINGUISHED SERVICE

Dr. Willard O. Thompson, chairman of Regional Committee No. 14 of the Committee for Wartime Graduate Medical Meetings, was recently awarded a Certificate of Distinguished Service by Major Gen. Russell B. Reynolds, commanding general, Sixth Service Command. According to the citation accompanying the award, "In 1942 the American Medical Association, in conjunction with the American College of Surgeons and the American College of Physicians, established a fund to provide postgraduate medical instruction for medical officers stationed throughout the Army. Dr. Willard O. Thompson, chairman of the Committee for Wartime Graduate Medical Meetings for Region No. 14, which includes Illinois and Wisconsin, obtained the services of prominent teachers and practitioners of medicine to lecture and conduct clinical exercises in the hospitals of the Sixth Service Command. He himself has actively participated in the teaching and by boundless energy and enthusiasm has maintained the continuity and high quality of the program. The medical officers of this service command as well as hundreds of civilian physicians who have attended the courses at army hospitals have universally expressed their appreciation for this unusual opportunity for postgraduate instruction, which has definitely raised the standard of medical practice in the Sixth Service Command. Dr. Thompson, as chairman of the committee, by his untiring efforts and devotion to this important program, has rendered distinguished service to the Sixth Service Command, and in recognition thereof the commanding general is pleased to present this citation."

BLINDED VETERANS ORGANIZE ASSOCIATION

One hundred soldiers who have lost their sight in the war recently organized a Blinded Veterans Association, the first of its kind in this country, to help blinded service men establish themselves as independent members of their home communities. The association will act as a clearing house for jobs for blinded veterans of this and World War I. The constitution of the Blinded Veterans Association forbids the acceptance of contributions and will be maintained only from fees and dues of members. The organization was set up at the Army's Old Farms Convalescent Hospital, Farmington, Conn. Mr. Raymond Frey, a former army lieutenant, who is now an instructor of the blind at Valley Forge General Hospital, Phoenixville, Pa., is chairman of the association.

MERITORIOUS SERVICE UNIT PLAQUE

Military personnel assigned to Dibble General Hospital, Menlo Park, Calif., Service Command Unit 1985, have been cited for "superior performance of duty" between Dec. 1, 1944 and Jan. 31, 1945 and authorized to wear the Meritorious Service unit insigne. Presentation of a Meritorious Service unit plaque to the Menlo Park army installation also was authorized by Major Gen. William E. Shedd, commanding general of the Ninth Service Command.

NEW DERMATOSES SLIDES TO AID INSTRUCTION

The Office of the Surgeon General reported recently that six sets of lantern slides on cutaneous disease have been completed by the Army Medical Museum and are ready for distribution. They will be lent to army teaching centers and are available for deployment teaching programs. These slides emphasize dermatoses which have been seen in tropical overseas theaters. All but three are in color.

COLONEL BLADES NAMED CONSULTANT

Lieut. Col. Brian B. Blades, M. C., who is chief of the thoracic surgical section of Walter Reed General Hospital, Washington, D. C., has been appointed consultant to the Surgeon General in thoracic surgery, in addition to his other duties.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Robert D. Bickel

Lieut. Col. Robert D. Bickel, formerly of Gallup, N. M., and now assigned to the Liaison Office at the American Medical Association, was recently presented with the Legion of Merit award "for exceptionally meritorious service in the performance of duty as commanding officer, —— Station Hospital during the period Jan. 1, 1943 to Oct. 13, 1944. Lieutenant Colonel Bickel (then Major) despite inadequacies of personnel and difficulty of supply while in India, has enlarged and expanded this hospital of a 50 bed capacity to meet rapidly increasing needs. He moved it from India to China, where the supply problem was even more acute, and continued its expansion. Because of his untiring efforts, efficient administration, devotion to duty and outstanding leadership, this hospital was able to perform its mission and also to meet extraordinary demands caused by the sudden unanticipated evacuation of patients from the hospital in East China and the Air Force dispensaries. This service reflects great credit both to Lieutenant Colonel Bickel and to the armed forces of the United States." Dr. Bickel graduated from Johns Hopkins University School of Medicine, Baltimore, in 1937 and entered the service March 10, 1941.

Captain Albert H. Meinke Jr.

Capt. Albert H. Meinke Jr., formerly of Detroit, was recently cited "for meritorious service in combat during the period Feb. 20 to Feb. 26, 1945 in the Apennine Mountains, Italy. During an attack, when mounting casualties crowded his aid station, and the enemy subjected his position to a terrific artillery barrage, Captain Meinke performed his duties as battalion surgeon with cool courage and skill. Laboring for more than forty-eight hours without rest, he gave the best medical assistance to each of the wounded and directed the disposition and evacuation of all casualties with commendable efficiency and promptness. By his tireless devotion to duty under the most distressing conditions, Captain Meinke saved many lives and prevented much pain and suffering. He has well earned the commendation and praise of all for his inspirational accomplishments, which are truly in keeping with the finest traditions of the Medical Corps." Dr. Meinke graduated from the University of Michigan Medical School, Ann Arbor, in 1943 and entered the service Aug. 4, 1944.

Captain Harlan Alfred Alexander

A Bronze Oak Leaf Cluster was recently awarded to Capt. Harlan Alfred Alexander, formerly of Minneapolis, for "heroic achievement in connection with military operations against the enemy on Oct. 24, 1944 during the Leyte Island operation. During a time when an infantry battalion was attacking north on the Buri airstrip, the launching of a severe enemy counterattack inflicted many casualties among the friendly forces and prompted an immediate withdrawal of the battalion. Captain Alexander, realizing the necessity for evacuating the wounded, and with the knowledge that front line protection had been withdrawn, maintained his aid station in the exposed area until all the wounded were evacuated to a place of safety. This action, with utter disregard for his own personal safety, was an impressive demonstration of courage on the part of Captain Alexander." Dr. Alexander graduated from the University of Minnesota Medical School, Minneapolis, in 1930 and entered the service Sept. 8, 1942.

Colonel Jarrett M. Huddleston

An Oak Leaf Cluster to the Silver Star was awarded posthumously recently to Col. Jarrett M. Huddleston, formerly of Washington, D. C. The citation accompanying the award read "for gallantry in action at ——, Italy, on Feb. 7, 1944. At about 08:15 Feb. 7, 1944 an enemy dive bombing attack caused considerable damage to buidings and vehicles, one of the latter being loaded with ammunition. Colonel Huddleston, who at the time was engaged on a tour of inspection of hospitals, came upon the scene at the time of the attack. With complete disregard for his own life and safety, he entered one of the buildings, then burning, to rescue a badly wounded soldier who was buried in the wreckage. Working with coolness and efficiency he evacuated the soldier, commandeered a vehicle and dispatched him quickly to a hospital. During all this time exploding projectiles and bursting shrapnel from a burning truck covered the area. Colonel Huddleston's calm and courageous action undoubtedly saved the life of the wounded soldier, prevented widespread confusion and was an inspiration to all present, reflecting the highest credit upon himself and is in keeping with the finest traditions of the Army of the United States." Dr. Huddleston graduated from George Washington University School of Medicine, Washington, in 1916 and entered the service the following year.

Captain Leon M. Swift

The Bronze Star was recently awarded to Capt. Leon M. Swift, formerly of Marysville, Calif., "for meritorious service in connection with military operations against an armed enemy. During the period of Dec. 29, 1944 to Jan. 13, 1945 Captain Swift, as platoon leader of the clearing platoon, worked tirelessly and very efficiently in treatment of battle casualties which passed through his station in great numbers. Although in poor health at the time, Captain Swift refused to be evacuated and worked for excessively long periods of time without regard for his health and personal comfort, and his timely and superior treatment of the great number of battle casualties resulted in the saving of many lives. His leadership and devotion to duty was an inspiration for the excellent functioning and operation of the clearing platoon. Captain Swift's outstanding professional ability, devotion to duty and disregard for personal welfare are in keeping with the highest tradition of the United States Army." Dr. Swift graduated from the College of Medical Evangelists, Los Angeles, in 1933 and entered the service May 2, 1942.

Captain Robert H. Draddy

The Bronze Star was recently awarded to Capt. Robert H. Draddy, formerly of New York, for "meritorious achievement in action" from Nov. 11, 1944 to April 23, 1945 in France and Germany. "As commanding officer of a collecting company," said the citation, "Captain Draddy discharged his duties in an exemplary manner throughout the period in which the division fought its way through the mountainous terrain of the Vosges into Germany and across the Rhine. During the bitterly contested crossing of the Neckar River at Heilbronn, Germany, he so well organized and directed the evacuation of casualties that despite long litter hauls and enemy action many wounded men arrived at the clearing station in less than two hours after their recovery. Captain Draddy's excellent utilization of personnel and equipment thus resulted in the saving of many lives in this and countless other actions." Dr. Draddy graduated from Cornell University Medical College, New York, in 1943 and entered the service Dec. 31, 1942.

Captain Hime Poliner

Capt. Hime Poliner, formerly of Easton, Pa., was recently cited for performing an appendectomy under difficult conditions on an LCI (L). According to the citation signed by Lieut. George Linton Jr., U.S.N.R., commanding the ship, the patient complained of sharp abdominal pains while the ship was off Mindoro Island, Philippine Islands, on April 11 last. "Capt. Hime Poliner, M. C., . . . being the only physician on board the ship, examined the patient and diagnosed the complaint as acute gangrenous appendicitis, necessitating an immediate appendectomy." The concluding paragraph of the citation read "It is the desire of this command to commend Dr. Poliner to his superior officers for the prompt and skilful action taken by him under these somewhat unique circumstances, as the appendectomy performed by Dr. Poliner is, to the best knowledge of this command, the first operation of its kind performed aboard an LCI (L)." Dr. Poliner graduated from Temple University School of Medicine, Philadelphia, in 1936 and entered the service in December 1942.

Major George M. Brother

George M. Brother, formerly of Indianapolis, was recently awarded the Bronze Star for developing an extremely effective malaria control program. He has been assistant surgeon at headquarters of the 15th AAF for some time. Dr. Brother graduated from the Indiana University School of Medicine, Indianapolis, in 1934 and entered the service Dec. 8, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Captain Howard K. Gray

The Navy Commendation Ribbon was recently awarded to Capt. Howard K. Gray, formerly of Rochester, Minn. Captain Gray, who was chief of the surgical service at the Navy Hospital, Aiea Heights, Hawaii, between August 1944 and May 1945, was commended for "devotion to duty, able leadership in coordinating the surgical service of the hospital and superior skill in his profession." He is now serving as chief of surgery at the U. S. Naval Hospital at San Diego. Dr. Gray graduated from Harvard Medical School, Boston, in 1927 and entered the service Dec. 26, 1941.

Lieutenant Commander Ralph C. Parker Jr.

Lieut. Comdr. Ralph C. Parker Jr., formerly of Boston, was recently awarded the Bronze Star "for meritorious service as senior medical officer attached to the U. S. S. *Arkansas* prior to and during the invasion of the coast of France on June 6, 1944. Skilled and tireless in the performance of duty, Lieutenant Commander Parker achieved exceptional success in training the personnel of the medical department for the prompt and expert care and treatment of casualties brought aboard during assault operations. His outstanding professional integrity and devoted efforts were responsible for the saving of many lives and in keeping with the highest traditions of the United States Naval service." Dr. Parker graduated from Harvard Medical School, Boston, in 1937 and entered the service July 2, 1938.

Lieutenant Joseph Rogers

Lieut. Joseph Rogers, formerly of Brooklyn, was recently commended, the citation reading "For distinguishing himself by heroism after his ship had suffered a damaging underwater explosion during the occupation of Kiska Island on Aug. 18, 1943. He worked heroically for a period of thirty-six hours administering expert medical treatment to men injured in the explosion. Medical treatment to these men was so ably administered that all injured men recovered. His conduct was at all times in keeping with the highest traditions of the naval service." Dr. Rogers graduated from Harvard Medical School, Boston, in 1941 and entered the service Oct. 5, 1942.

MISCELLANEOUS

CONTROL OF TYPHUS IN YUGOSLAVIA

The United Nations Relief and Rehabilitation Administration recently assumed leadership in the program for the control of typhus in Yugoslavia as part of its duties under the International Sanitary Conventions of 1944.

The United States of America Typhus Commission formerly led the control program in Yugoslavia, with UNRRA personnel assisting. The commission signed an agreement with Marshal Tito in January 1945 setting up the necessary arrangements for the work. Mass inoculation of the entire population of Bosnia and Herzegovina is well under way, and half a million people have been inoculated to halt the spread of endemic typhus in that area. DDT powder and vaccine were shipped to the area by plane so as to expedite the program. Twenty UNRRA doctors, nurses, sanitary engineers and other technicians are now at work as members of the health staff of the UNRRA Yugoslav mission. The takeover of the control program by UNRRA was completed July 1.

The first typhus epidemic of World War II in Yugoslavia was reported from the Partisan side in the winter of 1941-1942. The disease reached a peak in the section then known as "Independent Croatia" the following winter, when there were over 30,000 cases with more than 5,000 deaths among the civilian population in western Bosnia and Dalmatia. In central and eastern Bosnia typhus reached epidemic proportions in 1944.

Typhus broke out in 1941 in a large concentration camp in Serbia, where a number of gipsies were interned. It gradually spread over the country and in the winter of 1943-1944 there was a severe epidemic. With the arrival of the United States of America Typhus Commission last winter, modern methods of epidemic control were introduced. DDT insecticide powder is applied with hand or electric blow guns. Hundreds of people can be disinfested in a short time. No undressing, bathing and subsequent disinfection of wearing apparel is necessary.

Dr. W. A. Sawyer, director of the health division, expressed a hope that UNRRA, in carrying forward the work so well begun by the United States of America Typhus Commission, in cooperation with the health officers of the Yugoslav government, would be able to rid Yugoslavia of louse borne typhus and so preclude the possibility of future outbreaks.

CUBAN DOCTORS VOLUNTEER FOR WORK IN OCCUPIED EUROPE

Four Cuban doctors who have volunteered for duty in occupied Europe recently arrived in the United States for special studies at the University of Maryland before going to Europe for the United Nations Relief and Rehabilitation Administration. They are Drs. Amary Escalona, Oscar Ferrer, Rene Vallejo and Enrique Roig.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL June 30, p. 671)

CALIFORNIA

St. Luke's Hospital, San Francisco. Capacity, 225; admissions, 6,156. Dr. Howard H. Johnson, Medical Director (assistant resident—mixed service, disqualified for medical service).

DISTRICT OF COLUMBIA

St. Elizabeths Hospital, Washington. Capacity, 7,576 beds; admissions, 2,599. Dr. Winfred Overholser, Medical Director (intern).

ILLINOIS

Illinois Masonic Hospital, Chicago. Capacity, 186; admissions, 5,322. Mr. William H. Tenney, Superintendent (2 interns, October 1).

Oak Park Hospital, Oak Park. Capacity, 182; admissions, 5,479. Sister St. Colette, Superintendent (intern).

MASSACHUSETTS

Massachusetts General Hospital, Boston. Capacity, 480; admissions, 7,677. Dr. N. W. Faxon, Medical Director (interns and residents—anesthesia).

NEW JERSEY

Hackensack Hospital, Hackensack. Capacity, 300; admissions, 7,293. Mrs. Mary Stone Conklin, R.N., Superintendent (3 interns).

Passaic General Hospital, Passaic. Capacity, 275; admissions, 5,399. Miss Margaret A. Wallace, R.N., Superintendent (intern).

NEW YORK

St. Joseph Hospital, Far Rockaway. Capacity, 163; admissions, 2,671. Sister M. Bertrand, Superintendent (resident—mixed service).

Gouverneur Hospital, New York City. Capacity, 220; admissions, 3,221. Dr. O. I. Bloom, Medical Superintendent (intern).

New York State Reconstruction Home, West Haverstraw. Capacity, 310; admissions, 142. Dr. Kenneth S. Landauer, Acting Superintendent (residents—orthopedic surgery).

OHIO

Glenville Hospital, Glenville. Capacity, 135; admissions, 3,411. Mr. A. B. Harris, Superintendent (resident—mixed service).

PENNSYLVANIA

Northeastern Hospital, Philadelphia. Capacity, 102; admissions, 2,455. Mr. Charles H. Dabbs, Administrator (2 interns).

SOUTH CAROLINA

Greenville General Hospital, Greenville. Capacity, 355; admissions, 8,515. Mr. J. B. Norman, Superintendent (interns).

UTAH

Thomas D. Dee Memorial Hospital, Ogden. Capacity, 400; admissions, 8,405. Mr. Lawrence H. Evans, Superintendent (interns).

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

July 14, 1945.

Downey Charges Army Is "Hoarding" Doctors

Senator Sheridan Downey of California has charged that surplus army doctors in Europe are not working "more than an hour or two a day" and should be returned at once to this country to relieve the shortage of civilian doctors. As chairman of a special military affairs subcommittee investigating army use of doctors, he says that 7,000 doctors the Army promised to release by next May 1 should be returned to civilian service immediately. Mr. Downey said that since the investigation was reported in the army newspaper *Stars and Stripes* he has "had letters from doctors who are not working more than two hours a day—majors, colonels, captains." He said their morale "is breaking down" and letters from the Pacific reveal a similar situation there. Brig. Gen. Robert Berry informed the hearing that the War Department wants to return these doctors "as soon as it can," but that the commanding general of the European theater had advised the department on July 5 that "he flatly can't see any possibility of giving up these men immediately." The Army's "leisurely attitude" toward releasing surplus doctors was condemned by Senator Johnson of Colorado, and Senator Gurney of South Dakota suggested that something might be done to bring them home ahead of troops to be discharged. He reported complaints from 60 year old doctors who have "worked their hearts out" and want to be relieved.

Fewer Infantile Paralysis Cases Expected in 1945

Although the U. S. Public Health Service has warned of a seasonal rise in infantile paralysis, it also reports evidence that the number of infantile paralysis cases this year may be much fewer than the 19,053 recorded during 1944, which was the second highest number on record; 27,363 cases occurred in 1916. Through July 7 this year 1,424 cases had been reported from all parts of the country, as compared with 1,290 for the period last year. The excess for 1945 was explained by an unusually high incidence early in the year. Encouragement was reported from the fact that for the third consecutive week new cases have been fewer than for the corresponding week of 1944. Texas has been hardest hit so far this year; it reports a drop in new cases from 54 for the week ended June 30 to 21 for the week ended July 7. The worst epidemics last year were in North Carolina, Virginia, Kentucky and Erie County, N. Y. Health authorities believe that the high incidence in New York early this year was due to cases which started in 1944 but were not reported until this year. Health officials said that normally regions where the disease is widespread one season do not suffer visitations the next. Infantile paralysis is a warm weather scourge of countries in the temperate zone, with the United States probably the greatest sufferer. The malady usually tapers off with the arrival of cool fall weather.

Hospitals Included in Five Billion Dollar Postwar Construction

Erection of new hospitals and extensions to existing facilities are included in plans for a 5-billion dollar reserve of state and local construction projects now being assembled by a House postwar economic planning committee to stabilize the building industry after the war. This construction reserve, according to the committee, should be in addition to those plans for which local financing is available. Representative Colmer of Mississippi laid down three principles "as a foundation on which to erect a healthy national construction program: 1. The federal government should hold out no promise of aid to states or municipalities during the first peace years for financing their public works—especially since many of these are in a stronger financial position than before the war. 2. The federal government should assume leadership in building up an adequate reserve shelf of engineering plans . . . to lay the foundation for an orderly long term public works program and to provide a cushion against future drastic decline in the construction industry. 3. A construction policy board would be established in the executive office of the President to guide the public works program and to serve the construction industry in its efforts to maintain a healthy, stable growth in relation to national income.

Office Space Lacking in Capital for Returning Doctors

A serious shortage of office space in Washington, which is believed to exist in many other communities, is under study by the District of Columbia Medical Society. Col. A. Clagett Gray, medical officer of District Selective Service, is chairman of the Medical Society Committee on Service Physicians, which is endeavoring to obtain special preference for office space for service doctors returning to civilian practice. Some doctors who have already returned have been unable to find offices according to secretary Theodore Wiprud, who revealed that a survey of medical buildings and office space in other buildings revealed little hope of relieving the situation soon. He explains that Washington is now being served with a "minimum" number of doctors for its population and that the city needs the additional medical care which could be given by returning physicians and surgeons.

How Whole Blood is Shipped to the Pacific by Air

Whole blood is shipped successfully across the Pacific by air in an insulated container in which the bottled blood is placed in racks around a large compartment of cracked ice, according to Charles F. Belshaw, research consultant of the National Association of Ice Industries. He explained that although temperatures inside planes in the Pacific often go as high as 130 F., this method keeps the blood to be used in treating the wounded at a temperature between 40 and 45 F., which is necessary to keep it in usable condition. He also revealed that vegetable produce shipped bedded down in finely granulated ice keeps its freshness, crispness and vitamin C content over a longer period. This was learned from research conducted in twenty-one colleges. "This method of refrigerating produce with snow-ice is like the protective effect of the late spring snows on vegetation," Mr. Belshaw said. The research further showed that vitamin C retention in foods is essential in maintaining flavor and that keeping vegetables fresh through the use of snow-ice will bring food to the dinner table so that it tastes better and is better nutritionally.

Cleric Criticizes District Sterilization Bill

Rev. Patrick J. O'Connor, professor of sacred eloquence at Catholic University, has criticized what he terms efforts to "railroad" legislation to permit the sterilization of the feeble-minded. He spoke at the laying of a cornerstone of the new $240,000 graduate nurses' building and called attention to the House bill with the question "Is this the price of victory?" His remarks recalled the storm three months ago when the District of Columbia commissioners were under fire for allowing the sterilization of 3 patients at Gallinger Hospital. Subsequently Corporation Counsel Keech decided that there was no legal authorization even if a waiver by the patient or parents had been obtained.

Capital Notes

The gravest possible manpower shortage in local hospital history may close the tuberculosis ward in Gallinger Hospital, according to a report by Health Officer George C. Ruhland.

More than 8,000 of the 12,000 commitments to the District of Columbia jail in the past year were from alcoholism, and a sharp increase after the war is expected, reports Howard B. Gill, superintendent of penal institutions.

Gen. Jacob L. Devers, former commander of the 6th Army group in Europe and newly appointed chief of Army Ground Forces, recently visited wounded officers and men who had served under him, now hospitalized at Walter Reed Hospital.

Bureau of Information

SUMMARY SHEETS FROM ALABAMA, NEW YORK AND NORTH DAKOTA

Completed county summary sheets have been received from the Medical Association of the State of Alabama through Dr. D. L. Cannon, secretary; from the Medical Society of the State of New York through Dr. Walter P. Anderton, and from the North Dakota State Medical Association through Dr. L. W. Larson, secretary.

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

The accompanying table gives data from counties in each of these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Council on Medical Service and Public Relations

MEETING OF JUNE 21-22, 1945

The meeting of the Council on Medical Service and Public Relations was called to order by the vice chairman, Edward J. McCormick, Toledo, Ohio, in the Council offices, American Medical Association, Chicago. Present were Drs. McVay, McGoldrick, Adson, Lawrence, Bauer, West and Mr. Hendricks.

Election of Chairman and Changes in Council Personnel.—A letter of resignation as chairman was received from Dr. John H. Fitzgibbon, Portland, Ore. A motion was made by Dr. McVay, seconded by Dr. McGoldrick and carried, that a letter be sent to Dr. Fitzgibbon expressing appreciation of his services and untiring effort for the success of the Council. Dr. Fitzgibbon is to continue as a member of the Council.

A motion was made by Dr. McVay, seconded by Dr. Adson and carried, that Dr. McCormick be elected chairman of the Council.

A motion was made by Dr. McGoldrick and carried that Dr. McVay be vice chairman and a member of the executive committee of the Council. The executive committee of the Council is now composed of Drs. McCormick, McVay, Adson and Bauer.

During the meeting word was received that the Board of Trustees had elected Dr. William R. Brooksher, Fort Smith, Ark., a member of the Council to succeed Dr. Leathers, whose resignation had been accepted at the May 10-11 meeting of the Council, until the next session of the House of Delegates.

Meeting with the Board of Trustees.—Members of the Council met with the Board of Trustees.

The Board of Trustees addressed a communication to the Council concerning relationships of the Board of Trustees, the Council on Medical Service and Public Relations and the work of the Association.

Statements from Council to Board of Trustees.—The following day the Council again met with the Board of Trustees and presented a constructive program for medical care (see page 883 of this issue of THE JOURNAL), the Council suggestions relative to medical aspects of the Wagner-Murray-Dingell bill and the program of the Washington office.

The Board of Trustees approved the publication and distribution of the "Constructive Program for Medical Care" after being properly edited. The Board approved the Council suggestions relative to the medical aspects of the Wagner-Murray-Dingell bill. The Board approved the Washington office program, after discussion.

Informing County Societies of Council Action.—A motion was made by Dr. McGoldrick, seconded by Dr. McVay, and carried, that the Council's point of view in regard to pending legislation be forwarded to the chairmen of the legislative committees of the state societies. A motion also was made and carried that

the chairmen of the state legislative committees or their representatives be invited to attend a meeting in Chicago to discuss and plan for the better and wider dissemination of medical care for the people of this country.

Statement on Wagner-Murray-Dingell Bill.—A motion was made by Dr. McVay, seconded by Dr. McGoldrick, that the director of the Bureau of Legal Medicine and Legislation and the secretary prepare a statement on the Wagner-Murray-Dingell bill. Such a statement was prepared by the Council in 1943.

Speakers' Kits.—The Council is to stimulate the preparation of speakers' kits containing material which might be used by speakers before medical societies or lay groups in regard to the present Wagner-Murray-Dingell bill. These folders of material were collected and made available to speakers in 1943-1944 in Michigan and in Indiana. The Council is to obtain copies of these kits and suggests that similar kits be prepared for the 1945 bill by the various state legislative and public relations committees.

Service Plan Survey.—The preliminary chart that has been prepared on the service plans which are conducted under the approval of county and state medical societies was approved by the Council. This is to be checked with the various state and county plan managers and published in THE JOURNAL.

Journal Column with Regard to Medical Care and Hospital Insurance News.—Attention of the Council was called to the news column that appears under the Council on Medical Service and Public Relations heading in THE JOURNAL about hospital and sickness insurance. In addition articles are appearing under the heading of Medical Economics prepared by the Council summarizing reviews that are appearing in the *British Medical Journal* concerning the medical care programs of foreign countries. Suggestions were made that included in these should be summaries of the New Zealand and Australian medical care programs as they are appearing in the *British Medical Journal* and the *Lancet*.

Annual Report of Council.—A draft of the report prepared by Dr. Louis Bauer was distributed to members of the Council. It is to be reviewed by them and suggestions, corrections and additions sent to the Council office in order that a final draft of the report may be prepared. A suggestion was made by Dr. McCormick that the number of state and county societies addressed by Council members should be carried in this report.

Insurance Plan Advertisements.—The Board of Trustees referred to the Council for attention the question whether or not THE JOURNAL should carry advertisements for insurance plans for patients and stated that until principles were better established such advertisements could not be carried in THE JOURNAL. The Council approved the following statement: "The Council does not feel it can pass intelligently on the advisability of insurance advertising until an insurance bureau in the American Medical Association has been set up and proper standards for such plans have been determined. These standards cannot be determined *without the help of this Bureau.*"

Medical Care in Rural Areas.—Dr. McVay discussed the problem of medical care in rural areas. He told how this problem is being approached in Missouri. The Council suggested that Dr. McVay write a statement of some five hundred words in regard to this question, which might be submitted for publication under the Council heading in THE JOURNAL.

Committee to Function with Farm Bureau.—Announcements were made that the Board of Trustees had appointed a committee to be headed by Dr. F. S. Crockett of Lafayette, Ind., to cooperate with the Farm Bureau in working out medical care program. Dr. McCormick was placed on that committee as a representative from the Council. The Council is to offer its full cooperation to Dr. Crockett and his committee.

Health Insurance: An Inquiry into Some of the Factors and Forces Underlying the Demand for a Compulsory System.—Dr. Fishbein called the attention of the Council to an article entitled "Health Insurance" by Carl W. Strow and Gerhard Hirschfeld. The article has been read by members of the Council, and the Council approved its publication "for the information that it contains relating to the factors underlying the demand for federal sickness insurance."

Additional Employment for Council Office.—The Council suggested several names to be considered for employment as an assistant to the secretary and as director of the Bureau of Medical Economics.

Public Relations Charts.—Charts showing the relation of the Council on Medical Service and Public Relations to other bureaus and councils in the American Medical Association and to the state and county medical societies were discussed before the Council by Mr. T. V. McDavitt of the Bureau of Legal Medicine and Legislation. These charts are to be completed for presentation at the next meeting of the Council.

Return of Physicians in Service.—The Council discussed the possibility of the return of those physicians in military service who can be spared now that the war in Europe is over. The Council believes that the return of these men as soon as national security will allow is one of the essential factors in the entire picture of the medical care program of the country. The return of these men is one of the points covered in the Constructive Program for Medical Care outlined by the Council.

American Cancer Society.—Dr. McGoldrick, chairman of this committee, stated that he and Dr. Bauer had arranged a meeting for the coming week with Louis Neff, Director of the American Cancer Society.

Public Relations by County and State Medical Societies.—In answer to requests as to what a county medical society can do in regard to public relations, Dr. Harold Camp, secretary, Illinois State Medical Society, and James Kelley, executive secretary, Milwaukee County Medical Society, wrote letters to outline the work a county medical society might do in public relations work.

Regional Conferences.—The secretary was instructed to make recommendations in regard to locations and schedules for regional conferences to be held this fall and winter and have these ready for presentation at the next meeting of the Council.

Lending Library.—A recommendation was made by Dr. McGoldrick that the Council establish a lending library system on subjects having to do with medical care, compulsory health insurance and subjects especially relating to the field covered by the Council.

Radio Programs.—Dr. W. W. Bauer, Director of the Bureau of Health Education, discussed the problem of radio with the Council. The Council discussed the idea of a nationwide hook-up proposed at the conference of seventeen presidents held recently in Detroit, at the invitation of the Michigan State Medical Society. Dr. Bauer discussed the preparation of "platters" (radio transcriptions) by the Council.

EDWARD J. MCCORMICK, M.D., Chairman.
THOMAS A. HENDRICKS, Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

G. I. Bill of Rights

The chairman of the House Committee on World War Veterans' Legislation, Representative Rankin, has introduced H. R. 3749, a bill to amend the Servicemen's Readjustment Act of 1944. In addition to liberalizing the loan provisions of the existing law, the pending bill would effect certain changes in the provisions relating to the education of veterans. It would provide that courses may be initiated four years after the date of the discharge of the veteran or the termination of the present war and that no course shall extend beyond nine years after the termination of the war; it would provide for short intensive postgraduate or vocational training courses of not less than thirty weeks; it would authorize correspondence courses of education or training and would increase the subsistence allowance of a veteran undergoing training or pursuing a course of education from $50 to $60 a month, if the veteran is without dependents, and from $75 to $85 a month if the veteran has dependents.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Institute for Negro Physicians.—The state department of health cooperated with the Jefferson County Health Department and the Slossfield Health Center in a five day institute for Negro physicians of the state at the health center in Birmingham, July 9-13.

Changes in Health Officers.—Dr. Charles J. Fisher, formerly health officer of Tuscaloosa County, has been named to a similar position in Lauderdale County.——Dr. Sydney E. Langer, U. S. Public Health Service, has been appointed health officer of Calhoun County to succeed the late Dr. Artice E. Culberson, Anniston. Dr. Culberson died while serving as acting health officer of the county following the resignation of Dr. Julius E. Dunn, Anniston, as health officer of Calhoun and Etowah counties to enter private practice in Wetumpka. Dr. Elmus K. Hanby, Attalla, is acting health officer in Etowah County.

CONNECTICUT

Herbert Miller Goes to Kansas.—Dr. Herbert C. Miller Jr. has resigned as assistant professor of pediatrics, Yale University School of Medicine, New Haven, effective July 1, to become professor and head of the department of pediatrics at the University of Kansas School of Medicine, Kansas City. Dr. Miller graduated at Yale in 1934 and became a member of the faculty the following year.

DISTRICT OF COLUMBIA

Personal.—Dr. Alvin R. Sweeney, U. S. Public Health Service, has been appointed superintendent of the Gallinger Municipal Hospital.

District Election.—Dr. William P. Herbst Jr. was chosen president-elect of the Medical Society of the District of Columbia during the annual business meeting of the society in May. Dr. William E. Clark took over the office of president on July 1. Other officers include Drs. Fred A. J. Geier and Dorothy S. Jaeger, vice presidents; Coursen B. Conklin, delegate to the American Medical Association, and Archibald L. Riddick, alternate. Dr. William M. Ballinger had been acting as president of the society since Lieut. Col. James N. Greear Jr., M. C., was ordered overseas several months ago.

Progress of George Washington University Hospital.—The new George Washington University Hospital will be ready for occupancy in about eighteen months, according to the *Medical Annals*. The 400 bed structure, six stories high, will be equipped and managed as a teaching hospital, replacing an older building in use since 1898. It was made possible by a federal works agency grant in the amount of $2,700,000. Mr. Leo G. Schmelzer, who was recently appointed superintendent of the hospital, will supervise the construction and equipment, assisting Dr. Walter A. Bloedorn, dean of George Washington University School of Medicine and medical director of the hospital.

ILLINOIS

A. L. Bowen Dies.—A. L. Bowen, formerly director of the state department of public welfare, died in Elgin July 8, aged 75.

Counties Vote for Health Departments.—McLean and Montgomery counties voted in their June elections to establish their own permanent health departments under the provisions of the Searcy-Clabaugh county health department law. Other counties in the state which had previously voted for their own health units include Adams, DuPage, Edwards, Lawrence, Morgan and Wabash counties.

Temporary Health Commissioner for Peoria.—Dr. George P. Gannon, U. S. Public Health Service, formerly of Pittsburgh and more recently state venereal disease control officer in Denver, has been appointed temporary health commissioner of Peoria. He will continue in this position until the return of Dr. Sumner M. Miller, who is away because of ill health. Dr. John L. Lincoln, U. S. Public Health Service, held the position until the appointment of Dr. Gannon.

Chicago

The Allergy Unit at Illinois College of Medicine.—The University of Illinois College of Medicine has devised a plan for using in a consultative and teaching capacity its various departments. The Allergy Unit is composed of specialists in the fundamental and clinical branches of medicine. William H. Welker, Sc.D., head of the department of physiologic chemistry, is the director of research in the fundamental sciences. Under him are men who have gained recognition in bacteriology and immunology, in botany, in immunochemistry and in pharmacology. The clinical division of the Allergy Unit is headed by Dr. Ben Z. Rappaport, who will devote half of his time as director of clinical investigation and clinical head of the Allergy Unit. Dr. Adolph Rostenberg Jr., a dermatologist, is the associate director of clinical investigation and is appointed on a full time basis. In addition, there are in the Allergy Unit specialists in pediatrics, rhinology, ophthalmology and psychiatry. Supervised training by the staff in the fundamental sciences and by the clinical staff will prepare selected students in the subjects of biochemistry, immunology and botany as related to allergy. The primary training in allergy will be supplemented by training in clinical medicine, pediatrics and dermatology together with a fundamental understanding of otolaryngology and psychiatry. The period of training following the completion of an internship will be for three years on a full time basis or for an equivalent length of time if the training is taken on a part time (half time) basis. Two full time allergy research assistantships at $1,200 to $1,800 a year will be established. When the new building program is completed it is hoped that provision will be made for residence in the hospital for the senior of the two research assistants. During this period of training it is expected that the research assistant will be registered for graduate work and conduct research work equivalent to a year of graduate residence with the completion of a satisfactory thesis for the M.S. degree. The emphasis from the clinical standpoint will be placed primarily on clinical medicine, which training will be continued throughout the three year period. The first year will be devoted to clinical medicine and attendance in the Allergy Clinic. In addition, the student will attend the seminars in allergy, biologic chemistry and clinical medicine. In the second year the training in clinical medicine will be continued. Six months, half time basis, will be spent in pediatrics, four months in dermatology (half time) and two months on a half time basis in laryngology, rhinology and otology. Work on a research problem will be initiated. Attendance in the Allergy Clinic and the seminars in allergy, biologic chemistry and clinical medicine will be continued. A training course of six months will be given either as a separate subject to students who are well trained in internal medicine, pediatrics, dermatology or otolaryngology or as a subject supplementing any one of these courses taken by the student. Such a course will be planned especially for men who return from military service to give them an appreciation of allergy as a specialty, either separately or in conjunction with any of the related fields. The practice of allergy is primarily confined to office work. It is therefore one of the specialties suitable for physically handicapped physicians who might find it difficult to do the type of work requiring house calls. The large number of people who are allergic (about 10 per cent of the total population) and the relatively small number of specialists in this field will in all likelihood be additional reason for the choice of allergy as a specialty. The six month course will also meet the requirements of graduate students in pediatrics, dermatology or otolaryngology who may desire to study allergy as a supplementary subject. Qualified students may apply for study in biochemistry, bacteriology or immunology under the direction of the fundamental science staff of the Allergy Unit. A research assistantship ($1,800 a year) may be available for exceptional students who have an M.S. degree and who qualify for study toward a Ph.D. degree. The funds for the establishment of the Allergy Research Unit were provided by several donors. First, the nucleus and major portion was provided by the Field Foundation. This consisted of $23,000. Additional funds were obtained from the Asthmatic Children's Aid of Chicago. Finally, a large portion of the fund came from private patients who were interested in furthering investigative work.

INDIANA

School for Crippled Children Named for Harry Mock.—The Harry Mock School for Crippled Children was recently opened in Muncie under the sponsorship of the Delaware County Crippled Children's Association in cooperation with the city. The school was named for Dr. Harry E. Mock, Chicago, who was born in Muncie, where he later went to school. Dr. Mock, who served as a colonel in the medical corps during World War I, in charge of rehabilitation of disabled soldiers, wrote a "Creed of the Handicapped," which had been adopted as the motto for the school named in his honor. It reads:

> Once more to be useful; to see the pity in the eyes of my friends replaced by commendation; to work, produce, provide—seeking no favors and given none—a man among men in spite of my physical handicap.

Woman Enjoined from Practicing Medicine.—The state board of medical examination and registration was upheld in an injunction action seeking to restrain Della Moser, Decatur, from practicing medicine without a license. Judge W. H. Eichhorn of the Wells Circuit Court at Bluffton in his decision found in favor of the state medical board. According to newspapers, June 19, a motion by the defense attorney to arrest judgment on the findings was overruled and judgment was entered against Miss Moser prohibiting her from the practice of medicine without a license. The state contended, it was stated, that her treatment of persons at Decatur constituted the practice of medicine, while the defense contended that she did not go further than to manufacture medicines under a state permit authorizing her to do so. It was further contended that she sold customers only what they asked for and that she did not prescribe or give treatments.

KANSAS

Personal.—Dr. Clay E. Coburn, Kansas City, was recently guest of honor at a dinner given by the Kansas State Tuberculosis and Health Association in recognition of his service as an officer of the association for twenty-five years, during eleven years of which he held the presidency.——Dr. James D. Colt Jr., Manhattan, has been appointed a member of the state board of medical registration and education for a four year term expiring April 30, 1949. Drs. Harry L. Aldrich, Caney, and George I. Thacher, Waterville, were named to the board for three year terms expiring March 31, 1948.

Health Education Council Recommended.—The establishment of a Kansas Health Education Council was recommended recently, to be composed of twenty members, with Governor Andrew F. Schoeppel to serve as honorary chairman and with certain executive officers of the state board of health to serve as ex officio members. The recommendation was the result of a school health study which has been under way for the past year under the direction of Clair E. Turner, Dr.P.H. (THE JOURNAL, March 24, p. 723). In addition to the council it was recommended that an advisory committee be formed, the committee to consist of one member representing each of the fifty-three statewide organizations that have participated in the study.

MAINE

State Medical Election.—Dr. John O. Piper, Waterville, was chosen president-elect of the Maine Medical Association at its meeting of the house of delegates in Augusta, June 24. Dr. Adam P. Leighton, Portland, was installed as president. Dr. Frederick R. Carter, Portland, is secretary-treasurer. Speakers at the meeting were Dr. John J. Moorhead, New York, who discussed his impressions of the attack on Pearl Harbor, which occurred while he was there, and Dr. Albert S. Crawford, Detroit, who spoke on "Nerve Compression Syndrome of Lumbar Nerves: Modern Concepts and Surgical Treatment."

MINNESOTA

Resolution on Operating Room Privileges.—The board of directors of Asbury Hospital, Minneapolis, has approved for operating room privileges physicians of Minneapolis who are fellows of the American College of Surgeons, surgical specialists certified by the American boards and physicians of the city who, on the basis of training and experience in surgery, have been recommended by the operating room committee and the medical advisory board of the staff and the superintendent of the Asbury Hospital. This list shall be kept up to date in the records of the board of directors and a copy of this list shall be posted in the office of the operating room supervisor for guidance in scheduling operations. No operation shall be scheduled under the name of any doctor not on this list except by special permission from the superintendent of the hospital to the operating supervisor in each instance.

NEW HAMPSHIRE

Industrial Health Law.—Authority was granted to the State Department of Health of New Hampshire to engage in industrial hygiene by a law signed by Governor Charles M. Dale May 15. According to the *Industrial Hygiene News Letter*, rules and regulations relating to industrial health are authorized to be made by the health department and enforced by the state department of labor. Under the new act the health department may investigate all mines, quarries, foundries and industrial establishments employing five or more persons in manufacturing or processing of goods, in order to determine what health hazards may exist from noxious gases, fumes, dusts or other toxic materials. A penalty clause provides for fining employers who refuse to comply with rules and regulations formulated under the act, which took effect on its passage.

NEW YORK

School for Physical Therapists.—Albany Hospital, Albany, has established a new school for the training of physical therapists. The period of study is nine months, with a preclinical course of three months and a clinical course of six months. It consists of both didactic lectures and practical work carried on in the Albany Hospital and the Albany Medical College and affiliated institutions. The course will be given twice yearly, the first class to be admitted Sept. 12, 1945 and the second on March 13, 1946. Additional information may be obtained from Dr. John W. Ghormley, medical director of the school. Miss Catharine Graham is the technical director.

Personal.—Dr. Arthur J. Redmond has been appointed medical officer at the University of Rochester's college for men and for the men students at the Eastman School of Music. He succeeds Dr. Edwin Fauver, who recently retired as college physician and head of the physical education department but who will continue as an instructor in the medical school (THE JOURNAL, May 26, p. 300). Lieut. George P. Heckel (MC), U. S. Naval Reserve, will continue as medical officer for the Navy V-12 unit at the river campus and will share with Dr. Redmond the medical duties in connection with the welfare of the university's athletic teams.——Dr. Robert F. Korns, Amsterdam, former epidemiologist in the division of communicable diseases, New York State Department of Health, has been made acting associate director of the division for the duration of the war. He fills the vacancy that occurred when Dr. Herman F. Senftner, Albany, retired after twenty-eight years of service. Dr. Korns took over his new activities May 1.

New York City

Memorial to Physician.—The residuary estate, after a number of bequests, of Mr. Alfred F. Heim, who died June 11, will go to Cornell University for free scholarships to be known as the "Dr. John A. Heim Scholarship" in honor of his son, the late Dr. John A. Heim. Lenox Hill Hospital will receive a bequest of $5,000, also to be set up as a memorial to Mr. Heim's son.

Louis Pink Named Insurance Adviser for Philippine Government.—Louis H. Pink, president of the Associated Hospital Service of New York and formerly superintendent of insurance of the state of New York, has been given a leave of absence until September to serve the Philippine government as a special adviser in reorganizing the insurance industry of the Philippines.

Medical Service for Small Industries.—The first step in a proposed program to provide medical service for small industries has been taken by the special committee on industrial medicine of the Medical Society of the County of New York. Questionnaires are being issued to members of the society to determine what physicians would be interested to engage in this type of work and to assist the committee in developing a program to provide medical service for small industries.

Personal.—Erwin F. Fauser, executive vice president and general manager of William R. Warner & Company, Inc., manufacturing pharmaceutists, was elected president of the company to succeed Marvin R. Thompson, Ph.D., who resigned recently (THE JOURNAL, June 23, p. 605).——Dr. Samuel T. Orton, who gave the principal address during the commencement exercises of the University of Pennsylvania School of Medicine, Philadelphia, June 18, received on this occasion the honorary degree of doctor of science from the university.

Form Society for the Study of the Blood.—The Society for the Study of the Blood was organized at a meeting at the New York Academy of Medicine, June 14, with Drs. Alexander S. Wiener president, Paul Reznikoff vice president and Peter Vogel secretary-treasurer. The society will concern itself with problems in the allied fields of clinical and experimental hematology, blood grouping and transfusion. Three scientific meetings will be held a year. At the first meeting the speakers were Drs. Nathan Rosenthal on "The Development of Hematology in New York City"; Eugene R. Marzullo, "The Role of the Hematologist in the General Hospital," and Lester J. Unger, "Blood Banks of the Future."

Teaching and Research Fellowships Available Through Eye Bank.—Teaching and research fellowships to extend the knowledge and skill required for the delicate operation which restores sight to a blind person with a corneal defect through the grafting of healthy corneal tissue will be established in leading medical schools throughout the country by the Eye-Bank for Sight Restoration, it was announced July 16. The initial grant of $25,000 has been made by the Milbank Memorial Fund to enable the eye bank to function pending the time when the importance of the undertaking may gain recognition in widespread support, it was stated. It is hoped that financial support would be forthcoming from the general public in sums of any amount.

OHIO

Dickinson Models of Human Reproduction Acquired by Health Museum.—The Cleveland Health Museum has acquired the 100 R. L. Dickinson sculptural models for human reproduction for display and distribution to medical, nursing and health groups. The acquisition was made possible through the Prentiss Foundation, created by Elizabeth Severance Prentiss, who gave the original building to the museum, contributed to it while living and left an endowment on her death in January 1944. The collection, which is the result of sixty years of study and research by Dr. Robert L. Dickinson, New York, is based on life studies as contrasted with measurements based on postmortem examinations. It includes standard figures of the adult male and female and of the newborn baby; pregnancy and labor; anatomy of male and female reproductive organs; venereal diseases; some surgical operations; full-sized manikin for teaching medical students delivery; the World's Fair series of childbirth in successive stages; six small models for the doctor's desk for explanation to patients or students, and others for specialized uses. In the transaction the museum acquires possession and control of distribution of the models and an option on further additions to the collection, placing the museum in a position to make copies from the original for other institutions.

OKLAHOMA

Course in Surgical Diagnosis.—Dr. Patrick P. T. Wu, formerly assistant professor of surgery at Peiping Union Medical College and recently a fellow in surgery at the Mayo Clinic, Rochester, Minn., recently conducted a postgraduate course in surgical diagnosis in Guthrie, Stillwater-Cushing, Ponca City, Pawhuska and Bristow-Sapulpa. On completion of the course, which was given under the auspices of the Oklahoma State Medical Association, Dr. Wu was planning to return to Hong Kong, China.

Changes at University of Oklahoma.—The recent passage of appropriations bill 101 makes available $1,432,503 for construction of buildings, improvements and purchase of equipment for and at the University of Oklahoma School of Medicine and Associated Hospitals. In a report to the appropriations committee, Dr. Tom Lowry, dean of the medical school, recommended that the needs of the school of medicine be portioned in the following manner:

$375,000 for the school of nursing.
$175,000 for the isolation wing.
$75,000 for the Outpatient Department.
$400,000 for additional hospital beds.
$225,000 for an annex to the medical school.
$100,000 for remodeling, heating, power plant, laundry and shops.

The passage of house bill 200 changes the name of the Confederate Home, Ardmore, to the Southern Oklahoma Hospital, to be under the supervision of the University of Oklahoma. A $250,000 appropriation will be used to match a similar total from the citizens of Ardmore; this total, it is hoped, will be matched with a similar appropriation from federal funds. Dr. George N. Barry has resigned as medical director of the State University Hospital and the Crippled Children's Hospital in order to be available for a commission in the U. S. Navy. He has been a member of the staff at the hospital since 1937 and medical director since 1941. Dr. Barry has been granted a leave of absence from the medical school as assistant professor of clinical medicine.

RHODE ISLAND

Supreme Court Upholds Examining Board.—The supreme court of the state of Rhode Island has affirmed the action of the state board of examiners in medicine in revoking the license of Dr. Charles Jacobson, Providence. Dr. Jacobson appealed from the decision of the board to the supreme court. After a hearing before the full court, the appeal was denied in a rather lengthy opinion.

Francis Blake Receives Chapin Award.—Dr. Francis G. Blake, dean and Sterling professor of medicine, Yale University School of Medicine, New Haven, Conn., was presented with the Charles V. Chapin Memorial Award of the city of Providence for 1945, May 16, during the one hundred and thirty-fourth annual meeting of the Rhode Island Medical Society. The presentation was made by Hon. Dennis J. Roberts, mayor of Providence. Dr. Blake gave the annual Charles V. Chapin Oration before the medical society, on "Some Recent Advances in the Control of Infectious Diseases." The presentation of the award followed the oration. The award and the oration honor the late Dr. Chapin, who was superintendent of health of Providence for forty-eight years.

TEXAS

Proposed Advisory Council.—Dr. Edward H. Cary, president of the Southwestern Medical Foundation, Dallas, announced recently that an advisory council was to be formed soon to help acquaint the public of the Southwest with the program to build a great medical center in Dallas, it is reported. Both lay and medical representatives from each county of Texas and from adjoining states which the medical center proposes to serve will comprise the council.

Personal.—Dr. John T. Lawson, Bowie, was recently appointed a member of the state board of medical examiners for a term of six years. Dr. Lawson served as a member of the board from 1936 to 1942.——Dr. Tip M. Collins, Big Spring, recently completed fifty years in the practice of medicine.——Dr. Henry A. Petersen, Houston, was elected president of the Houston School Board recently.——Dr. Benjamin F. Arnold was recently appointed health officer of Greenville.——Dr. David Grady Deaton, Houston, has been appointed full time director of the Harris County Public Health Unit.

Merger of Hospitals.—The Medical and Surgical Memorial Hospital, San Antonio, operating under a nonprofit charter, has absorbed the Physicians and Surgeons Hospital. The trustees have arranged to erect a clinic building and establish a medical center operated on a nonprofit basis. The clinic will be supported by the hospital until it can become self sustaining, but it will not be run as a part of the hospital. Work will begin as soon as possible on a three story addition to the Medical and Surgical Hospital office building to provide accommodations for the clinic. According to the San Antonio *Evening News*, June 29, the enlarged hospital will have 215 beds. There are 150 at the Medical and Surgical Hospital and 65 at the Physicians and Surgeons Hospital. The two properties, situated on the opposite sides of Camden Street, may be linked by an underground passage. The Medical and Surgical Memorial Hospital was organized in 1927; the present organization was created in 1934 and was issued a charter by the state.

WEST VIRGINIA

Personal.—Dr. Harry A. Garrison has resigned as superintendent of the Weston State Hospital (mental), Weston, effective July 1, having held the position since Aug. 1, 1943, when he succeeded Dr. John E. Offner, Weston, who resigned to become state health commissioner. Dr. Homer O. Van Tromp, French Creek, has been named acting superintendent.

State Association Creates New Committees.—Dr. David Salkin, superintendent of Hopemont Sanitarium, Hopemont, has been named chairman of the new tuberculosis committee created by the house of delegates of the West Virginia State Medical Association at its meeting in May. Other members of the committee include Drs. Eustace T. Goff, Parkersburg; John N. Reeves, Charleston; George E. Gwinn, Beckley, and Sarah Elizabeth McFetridge, Shepherdstown. The new committee on relocation and reestablishment of doctors returning from service was also created with Dr. Wade H. St. Clair, Bluefield, as chairman. Other members include Drs. James P. McMullen, Wellsburg; Benjamin I. Golden, Elkins; Thomas Kerr Laird, Montgomery; Eugene C. Hartman, Parkersburg, and Hugh A. Bailey, Charleston.

HAWAII

Board of Health Publishes Annual Report.—The board of health of the Territory of Hawaii has issued its annual report for the fiscal year ended June 30, 1944. Dr. Charles L. Wilbar Jr., Honolulu, president, emphasizes that the report covers a wartime period. Infant mortality, maternal mortality and stillbirth mortality reached new all time lows during the year. The infant mortality rate was 31.3 per thousand live births as compared with 40.2 for the previous year and the previous record low of 38.6 for 1942. The maternal mortality rate was 1.97 per thousand live births compared with 2.28 for 1943 and the previous record low of 1.98 for 1941. The stillbirth mortality rate was 16.1 per thousand live births compared with 17.9 for 1943 and the previous record low of 17.39 for 1941. The overall civilian death rate in the period reached an all time low of 6.1 per estimated thousand of population, which, according to the report, is a lower death rate than has ever been recorded for any state. It is pointed out, however, that this does not mean that people are less likely to die in Hawaii than on the mainland but rather that the low death rate reflects the presence of large numbers of young people. The overall death rate including military personnel would be 7.4 for the year if the same number of persons were included as in prewar days, but this is a misleading figure as it includes military deaths from the whole area without considering the present military population. Deaths of military personnel stationed in the area are reported to the health department, but, according to the record, the department has received no figures on military population since the beginning of the war. The report states that accidental deaths have moved into first place instead of deaths due to heart disease in the ten leading causes of death for the 1943-1944 fiscal period. Deaths from tuberculosis have moved into fourth place ahead of deaths due to congenital malformation and diseases in early infancy. The figure on accidental deaths is somewhat misleading in the overall picture in that several large scale military accidents are included. If these were excluded, accidental deaths would be in fifth place. The ten leading causes and their rates for 100,000 of population are:

Accidental deaths 150.9 as compared with 112.6 for the previous year.
Heart disease 125 as compared with 121.1 in 1943.
Cancer 76.5 as compared with 63.5 in 1943.
Tuberculosis 57.6 as compared with 56.6 in 1943.
Congenital malformations and diseases of early infancy 53.1 as compared with 61.2 in 1943.
Nephritis 48.2 as compared with 47 in 1943.
Cerebral hemorrhage 41 as compared with 43.6 in 1943.
Pneumonia 32.2 as compared with 35.5 in 1943.
Suicide 20.1 as compared with 20 in 1943.
Diabetes mellitus 16.6 as compared with 16.5 in 1943.

GENERAL

American-Soviet Medical Society in New Offices.—As of September 1 the new address of the American-Soviet Medical Society will be 58 Park Avenue, New York 16. The offices will be located in the American Russian Institute Building. The society will occupy the entire sixth floor penthouse and will have facilities for its library and research workers, business office and editorial departments.

Biography of Dr. Joseph B. De Lee.—Authors are now at work on a biography of the late Dr. Joseph B. De Lee. They are anxious to receive copies of correspondence or other documentary material which would be useful for inclusion in such a biography. Material may be sent to Dr. Sol. T. De Lee at 5028 South Ellis Avenue, Chicago. Any material that is sent will be carefully preserved and will be returned on request to those who sent it. Due acknowledgment will also be made for such material as is used.

Changes in Rockefeller Institute.—The board of scientific directors of the Rockefeller Institute for Medical Research, New York, announces the following promotions and appointments, among others:

Dr. Charles L. Hoagland, New York, to member.
Lyman C. Craig, Ph.D., New York, to associate member.
Lewis G. Longsworth, Ph.D., New York, to associate member.
Theodore Shedlovsky, Ph.D., New York, to associate member.
Dr. Paul B. Hamilton, New York, to associate.
C. Arthur Knight Jr., Ph.D., Princeton, N. J., to associate.

New appointments include:

Henrik Dam, D.Sc., Rochester, N. Y., associate member.
Dr. Maclyn McCarty, New York, associate.

Narcotic Violations.—The U. S. Bureau of Narcotics announces the following actions:

Dr. Henry C. Chalmers, Brookneal, Va., pleaded guilty in the U. S. District Court at Lynchburg, Va., June 4 to violation of the internal revenue code; his sentence was suspended and he was placed on probation for a period of three years on condition that he surrender his narcotic special tax stamp.

Dr. Edward Harmon Teed, Coeur d'Alene, Idaho, was convicted at Coeur d'Alene of violation of the federal narcotic law; on June 2 he was sentenced to a term of one year and one day and was fined $2,500. The penitentiary sentence was suspended and Dr. Teed was placed on probation for a period of one year.

Dr. Henry Raymond Gross, Chicago, pleaded guilty to violation of the federal narcotic law and on June 1 was sentenced to a term of three years; his sentence was suspended and Dr. Gross was placed on probation for a period of three years.

Dr. James Franklin Johantgen, Talladega, Ala., pleaded guilty in the U. S. District Court to violation of the Harrison narcotic law and on June 8 was fined $200 and placed on probation for a period of five years.

Dr. Benjamin F. Lazenby, Treece, Kansas, pleaded guilty in United States District Court at Wichita, Kan., to violation of the Harrison Narcotic Law and on May 7 was fined $100.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended July 7 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Maine	1	West Virginia	2
New Hampshire	2	North Carolina	1
Vermont	..	South Carolina	6
Massachusetts	1	Georgia	5
Rhode Island	..	Florida	..
Connecticut	7	Kentucky	1
		Tennessee	13
New York	21	Alabama	5
New Jersey	10	Mississippi	1
Pennsylvania	..		
		Arkansas	..
Ohio	5	Louisiana	3
Indiana	..	Oklahoma	6
Illinois	2	Texas	21
Michigan	3		
Wisconsin	..	Montana	1
		Idaho	..
Minnesota	..	Wyoming	..
Iowa	2	Colorado	..
Missouri	1	New Mexico	..
North Dakota	1	Arizona	..
South Dakota	..	Utah	..
Nebraska	..	Nevada	..
Kansas	1		
		Washington	..
Delaware	1	Oregon	..
Maryland	3	California	18
District of Columbia	..		
Virginia	5	Total	154

Basal Temperature Records to Aid Infertility Treatment.—A basal temperature record to aid in determining the probable time of ovulation in individual women is being made available by the medical committee of the Planned Parenthood Federation of America to physicians interested in the treatment of infertility and the planning of conception. As reported by Dr. Pendleton S. Tompkins, Philadelphia, in THE JOURNAL (March 11, 1944, p. 698) it has been found that an accurate daily record of basal temperature is valuable in estimating the optimal time for conception. There is a slight rhythm of variation in the normal temperature of a healthy woman, the temperature being lower during the first half of the menstrual cycle than during the latter half. The transition from the lower level to the higher one occurs at about the time of ovulation. In many cases the temperature will show a sharp drop and then shoot immediately to the higher level, which can be taken as an indication that ovulation is taking place. As the variation for the entire cycle may be less than half a degree, the patient must be provided with complete instructions and forms with which to plot her temperature accurately. The temperature is taken rectally each morning immediately on awaking before the patient has got out of bed, talked, eaten, drunk or smoked. The charts, as provided by the Planned Parenthood Federation, provide for a six months record. They indicate the calendar months, the length of the individual cycle and the number of days backward from the onset of the menses at which ovulation can be estimated to occur. The charts, together with the instruction forms for patient use, are available at cost through the medical department, Planned Parenthood Federation of America, 501 Madison Avenue, New York 22.

FOREIGN

Three Medical Schools to Be Opened in Reich.—Three of seven German medical schools, including the University of Heidelberg, will open September 1, Major Gen. Morrison C. Stayer stated July 15, if the necessary equipment, a faculty and coal to heat the buildings can be assembled, newspapers reported. General Stayer, chief of public health branch G-5, United States forces in the European theater, said there was a serious need in Germany for well educated physicians and surgeons, as German medicine declined badly during the Hitler period. He said that in order to protect the health of allied troops it is necessary that German health be kept at a high level. He added that many German prisoners were in bad health. General Stayer said that present plans call for the matriculation of 300 doctors for advanced training at Heidelberg, 500 students at Marburg University and 300 students at Erlangen University, adding that the other schools were too badly damaged to function.

June 16, 1945.

The Teaching of Pediatrics

A pediatric committee of the Royal College of Physicians has presented an important report on the teaching of pediatrics. It suggests that the student's attention should be directed to the growth and development of children while he is still learning biology, physiology and anatomy and that the diseases peculiar to childhood should find a place in his studies of pathology and psychology. In his midwifery course he should be taught by a pediatrician about health and disease in the newborn. He should also spend eight sessions at a child welfare center, where he will be taught by a pediatrician or a suitably qualified maternity and child welfare officer. Courses in the care of the newborn and in child welfare should precede his course in general clinical pediatrics, which should occupy not less than a third of his whole time given to clinical medicine and should include a resident period of a month. In the study of social medicine the social services dealing with children should be given proper weight, so that the student may gain some insight into the school medical service, child guidance centers and children's courts.

THE TEACHING UNIT

The report holds that a hospital center, closely linked to a university and with a separate children's hospital attached to it, has much to recommend it. A university department of pediatrics, housed in a children's hospital, would forward teaching and research. Alternatively the university pediatric department might be developed as part of a general undergraduate teaching center admitting 80 to 100 students a year. In any case it should have at least 100 beds for general medical and surgical cases and possibly additional beds for tonsillectomy. At least 20 more beds should be set aside for infectious diseases, and the department should be linked to an appropriate fever hospital. Students should also have access to rheumatic heart homes, orthopedic hospitals and institutions for tuberculous children, so that they can study disease in childhood, and they should see rehabilitation applied in convalescent homes. In London much larger children's units will have to be developed in many medical schools; meanwhile students should get the necessary experience in children's hospitals. In provincial schools the children's hospitals will provide the main teaching in pediatrics, though these should in due course become university centers. The staff of the children's department should consist of a whole time director of professional rank, a whole time senior assistant, a registrar and a resident house officer. Also there should be two part time pediatricians of the standing of physicians or assistant physicians. A senior pathologist should take a special interest in the pathology of children's diseases, and similarly a senior radiologist in x-ray examinations.

Fellowships to Promote the Study of the Maintenance of Health

The Nuffield Foundation announces yet another benefaction. It proposes to award a number of medical fellowships to help promising men and women who wish to follow an academic career in social medicine, child health, industrial health and psychiatry to obtain at home or abroad the necessary postgraduate training and experience. More men and women trained in research and teaching are needed to secure the continued advance of medical knowledge and the standard of medical education. The foundation believes that there is a special need for carefully selected persons to have opportunities for studies which relate to the promotion and maintenance of health as distinct from the recognition and treatment of established disease. It hopes that the fellowships being offered will help to meet this need.

Normally the annual value of a fellowship will be between $2,500 and $4,000. It may be awarded for one or more years but as a rule for not longer than three years. Candidates must hold a university degree in medicine registerable in Britain and have had general clinical experience since qualification. In order that doctors serving overseas may not be at a disadvantage, the trustees have refrained from requiring applications to be submitted by a specified date. Medical officers serving with the armed forces may apply now for fellowships tenable on demobilization.

Emergency Rations for Polar Flights

For the polar flights of the British airplane *Aries* it was decided to provide emergency rations sufficient to last the crew of 9 for twenty-eight days. These were designed and prepared by the Low Temperature Research Station of the Department of Scientific and Industrial Research in consultation with Wing Commander Macrae of the Air Force Institute of Pathology and Wing Commander Winfield of the Air Force Institute of Aviation Medicine, who was medical officer on the flights. As the normal rations would have been too heavy and bulky, dehydrated foodstuffs were adopted. These were in the form of 2 inch tablets wrapped in waxed films. Each on addition of water gave a ready made meal and there was sufficient range to provide four different menus. For example one menu for lunch was meat and vegetable stew, fruit, biscuits, butter and tea. The total weight of the rations was 393 pounds. It was found that rations for two days could be packed in a standard 4 gallon can, which not only was convenient but also could be gas packed to ensure that the food remained in the best condition possible.

Pulmonary Embolism in Liberated Prisoners of War

In a communication to the *Lancet* (June 2, p. 703) H. L. Miller calls attention to a condition that does not seem to have been previously observed in the war. Between May 1 and May 9 about 300 men were admitted to a hospital in this country suffering from the effects of privations as prisoners of war in Germany. About 200 were stretcher cases. In only 2 was the malnutrition severe enough to cause anxiety, but it was noticed during the first week that the majority had fever. One of them died in five minutes of pulmonary embolism, which was confirmed by necropsy. He had been allowed up for a day or two but had been put back to bed because of recurrence of edema of the legs. Nine days after admission another man died of pulmonary embolism six hours after the first manifestation. The question arose whether some of the symptoms and signs noted in the other men were not also due to pulmonary embolism. Most of the men had marched 500 to 1,000 miles between January and May on very short rations. During the last month of the march almost all of these developed diarrhea and swelling of the legs. The edema was usually limited to the lower shin but sometimes extended above the knee and in some was asymmetrical. Among the symptoms which they developed were paroxysmal dyspnea while at rest, chest oppression or pain, palpitation, cough (with hemoptysis in at least 1 case) and sudden collapse. The diagnoses made by the medical officers who examined the prisoners after liberation included pleural effusion, bronchitis, bronchopneumonia, lobar pneumonia and pulmonary tuberculosis. There were cases of sudden death and "pneumonia that kills in a few hours."

The signs remaining in the chest on admission to the hospital were in some attributed at first to unresolved pneumonia or atypical pneumonia, but the hospital staff now suspect that at least a proportion were the result of pulmonary infarction.

Some of the other signs so often seen in these ex-prisoners—slight cyanosis of the lips, pyrexia, tachycardia—may have been caused by small emboli without infarction. Paul White, who believes that pulmonary embolism commonly goes unrecognized, states that its principal cause is thrombosis of the leg veins, beginning as a rule in the calf and extending to the long saphenous and femoral veins. Such thrombosis would explain the edema developing in these prisoners as their malnutrition increased. After the war of 1914-1918 an increase of pulmonary embolism was attributed by Burwinkle to malnutrition.

PARIS

(From Our Regular Correspondent)

June 17, 1945.

Repatriation

The problem of repatriation of prisoners of war, of political or racial deportees, of supposedly voluntary workers and those recruited by force, who find themselves in Germany, presents an urgent problem to the French government. Even if limited to its health aspects and the demographic consequences, this problem is immense. Arrangements had been made and a plan of action decided, but the débacle of Germany has been so rapid and the prisoners and their families are so anxious to be reunited immediately that all plans were sidetracked.

There were various groups to be repatriated. The sick and wounded numbered about 250,000; more had already been cared for in Germany and had been liberated through the intervention of the International Red Cross. Others were still under treatment in German hospitals but could not be transported. There were many political transportees and "voluntary" workers. The majority of them were not patients in the strict sense of the term, but the suffering which they had to endure makes them practically convalescents, who have to be treated with special consideration. There were a million of such convalescents.

The return of these exiles took place by land, by sea (especially those who were liberated by the Soviet armies) or by air. Many of them had at the time of their liberation started on foot toward France, escaping from all control. It has been estimated that there were 15 million foreigners in Germany, and about 6 million of them spontaneously took to the road.

About 150 advance posts were organized quickly on the German roads, where the first selection was assured and where some urgent care could be given. There the repatriates were given instructions and directions. At the border itself, at the principal points of arrival by sea, by land and by air, health stations were created which directed them to regulatory stations as the last halting place before their return home. These health stations not only had to assure the administrative registration of the repatriates but also had to determine the control of this heterogeneous mass of refugees, their present and future health, the immediate care to be given them, the supervision to which they had to be subjected on their way home, their present capacity for work and the recuperation from which they were to benefit. The health supervision which they required was assured by the local health authorities, and a new examination was planned after six months. It was necessary that the examination on entrance into France should be complete and made moreover with all the caution merited. Everything was done in as simple a manner as possible to avoid any unnecessary delay.

They proceed first to the police department, where after identification their administrative papers are set up. Then they are undressed and their clothing is disinfected either by DDT or by fumigation. Then they receive a prolonged hot shower and a thorough soaping, followed by drying in hot air after a careful rinse. At this time those with scabies were marked and were painted with benzyl benzoate. Then came weighing and measuring and vaccination against smallpox. An orderly obtained 10 drops of blood from the ear lobe, and the slide with this blood was sent to the laboratory for a Kline test, which was chosen because it is especially rapid and sensitive. After this the medical examination is completed by roentgenography or by fluoroscopy if indicated by special examinations.

With the health record established, the repatriates are directed either to the hospital if they need treatment urgently or for a more thorough clinical examination, while the rest are sent to the regulatory station for their return home.

TUBERCULOSIS

Some 2,500,000 persons had to be examined rapidly. The first step was to make an x-ray examination. It was impossible to carry this examination out in Germany, where equipment and personnel were lacking. The task was performed in the frontier posts. Roentgenography is preferred over fluoroscopy because it is made more easily on large numbers and there remains an authentic document. Fluoroscopy is reserved for particular cases. A regular control is assured to the personnel who work in the radiologic crew. This systematic search for tuberculosis has proved fruitful; according to preliminary statistics on 24,695 repatriates of the department of the North, the mortality rate and the morbidity were double that in the other war. After the examination with x-rays, all the suspected cases are called to the attention of the health office of their home district and they will be subject to inquiry and supervision and will receive care when they need it. Convalescent homes and sanatoriums will be open for them.

SYPHILIS

Even when the presence of a contagious lesion was established, the serologic reaction was determined. Treatment was not enforced nor was return home delayed. Those infected were urged to obtain treatment. The health authorities at the patient's home were notified for future supervision.

CANCER

The great majority of repatriates are young men. Thus it was the more surprising to detect in them carcinomatous manifestations. Cancer, of course, is not necessarily a disease of mature age. Unfortunately the means of rapid and systematic detection of cancer have not been perfected as yet.

Marriages

RUSH E. NETTERVILLE, Wilkinson, Miss., to First Lieut. Frances Foil McAllister of Mount Pleasant, N. C., in Epinal, France, April 12.

GUTHRIE YOEHLEE GRAVES, Bowling Green, Ky., to Miss Elizabeth Hannan Ellis of Hopkinsville, June 9.

JAMES C. SPALDING, Lebanon, Ky., to Miss Arminta Scott of Corinth, Miss., in Nashville, Tenn., June 2.

CHARLES SAMUEL MCCAMMON, Maryville, Tenn., to Miss Mary A. Thornburgh of Knoxville, June 14.

HAROLD FREDERICK BERTRAM, Memphis, Mo., to Miss Margaret Baden Patterson of Baltimore, May 7.

JOHN HARVEY NICHOLSON, Statesville, N. C., to Miss Gertrude James May in Richmond, Va., June 2.

GEORGE H. MCSWAIN, Paris, Tenn., to Miss Mary Jane Allred of Bowling Green, Fla., May 27.

JOHN MILTON MOOK, Metuchen, N. J., to Miss Jean Marie Wallace of Nashville, Tenn., June 12.

JOHN COVINGTON TINSLEY Jr., Lynchburg, Va., to Miss Ellen Luberger of Wyoming, Ohio, June 9.

FRANK J. PICKETT, Joplin, Mo., to Miss Yvonne Best of Vandalia, Ill., in St. Louis, June 8.

RUSSELL DORRIS WARD to Miss Margaret Virginia Bowen, both of Nashville, Tenn., June 8.

Deaths

Horace Newhart ⊕ Minneapolis, authority in otology, died July 9, aged 72, of cancer.

Dr. Newhart was born in New Ulm, Minn., Dec. 9, 1872. He studied in the New Ulm public schools, Carleton College and Dartmouth College and graduated at the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1898. Intermittently until 1912, when he joined the faculty of the University of Minnesota School of Medicine, he engaged in graduate study in Vienna. At the time of his death he was professor emeritus in otolaryngology at Minnesota, where for a long period he had been head of his department, and at the University of Minnesota Graduate School, Minneapolis-Rochester. He had been a member of the staff of the Glen Lake Sanatorium, Oak Terrace, University of Minnesota, Northwestern, St. Barnabas and the Abbott hospitals.

His many affiliations included service as consultant on audiometers and hearing aids of the Council on Physical Medicine of the American Medical Association and as president of the American Laryngological, Rhinological and Otological Society, American Acoustical Society, Minnesota Academy of Ophthalmology and Otolaryngology and the Minnesota Academy of Medicine, a fellow of the American College of Surgeons and a member of the committee on conservation of hearing of the Minnesota State Medical Association. For many years he was consulting otologist to the public schools in Minneapolis. Dr. Newhart was one of the first to be certified as a specialist by the American Board of Otolaryngology.

Exceedingly active in promoting the importance of testing the hearing of school children, Dr. Newhart had only recently completed with Scott N. Reger, Ph.D., a "Syllabus of Audiometric Procedures in the Administration of a Program for the Conservation of Hearing of School Children" while serving as a member of the executive committee of the committee on the conservation of hearing of the American Academy of Ophthalmology and Otolaryngology. In 1937 he was given honorable mention by the Minnesota State Medical Association for his exhibit on the prevention of deafness.

Henry Onslow Smith, Hudson, N. H.; Bellevue Hospital Medical College, New York, 1887; member of the American Medical Association, the New Hampshire Historical Society and the New England Historic Genealogical Society; served as president and for many years a member of the board of trustees of the New Hampshire Medical Society, from which he had received a fifty year medal in 1937; served as a member of the school board, trustee of the public library and member of the board of health; on the staff and trustee of the Memorial Hos-

CAPT. FREDERICK EMIL BARTHES
M. C., A. U. S., 1908-1944

CAPT. JAMES S. BERTOGLIO
M. C., A. U. S., 1917-1945

LIEUT. COMDR. JOHN W. FISH
(MC), U.S.N.R., 1908-1944

KILLED IN ACTION

Frederick Emil Barthes, La Grange Park, Ill.; Loyola University School of Medicine, Chicago, 1942; interned at the Columbus Hospital in Seattle; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 8, 1942; promoted to captain; killed in action in Belgium Dec. 18, 1944, aged 36.

James Stephen Bertoglio, Butte, Mont.; University of Michigan Medical School, Ann Arbor, 1943; interned at the City of Detroit Receiving Hospital; began active duty in the medical corps, Army of the United States, on Dec. 26, 1943; later promoted to captain; killed in action in Germany January 10, aged 27.

John Winston Fish, Louisville, Ky.; University of Louisville School of Medicine, 1934; member of the American Medical Association; on the staff and formerly an intern at the Kentucky Baptist Hospital; served a residency at the Eye, Ear, Nose and Throat Hospital in New Orleans, and the Methodist Episcopal Deaconess Hospital; on the staffs of the Norton Memorial Infirmary and the Jewish Hospital; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve on Feb. 4, 1942; reported to Marine Corps Base, San Diego, Calif., for active duty; went to the Naval Air Station, Pensacola, Fla., for temporary duty in attendance on a course of instruction leading to the designation of aviation medical examiner; from there he went to Naval Reserve Air Base, Oakland, Calif., for duty with designation of "qualified medical examiner"; later ordered to Naval Air Station at Oakland for duty involving flying with designation of naval flight surgeon; ordered to report to an air group for duty involving flying on board a vessel; promoted to lieutenant commander on March 1, 1944; awarded the Asiatic-Pacific Area Campaign Medal and the Purple Heart; died in the Pacific area Nov. 25, 1944, aged 36, of blast concussion and bomb asphyxiation while on duty in the battle dressing station of an aircraft carrier.

pital and on the staff of St. Joseph's Hospital, both in Nashua; chairman of the local committee on public safety during World War I and chairman of the emergency medical service of civilian defense during World War II; in 1927 compiled and published "The Early Story of Hudson, N. H."; edited, amended and brought up to 1941 "The Story of the New Hampshire Medical Society"; died May 14, aged 80.

Grover C. Daniel, Whipple, Ariz.; Loyola University School of Medicine, Chicago, 1919; member of the Washington State Medical Association and the American Medical Association; served in the medical corps of the U. S. Army from September 1917 to December 1918; formerly assistant surgeon in the U. S. Public Health Service Reserve; manager of the Veterans Administration Facility; formerly manager and clinical director of the Veterans Administration Facility in Walla Walla, Wash.; at one time on the staff of the Veterans Administration Facility in West Los Angeles, where he died May 16, aged 53, of abdominal carcinomatosis.

Henry Houston Ogilvie ⊕ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1910; fellow of the American College of Surgeons; served during World War I; in July 1943 cited by the office of civilian defense in Washington for his service while chairman of the local emergency hospital corps; served as surgeon at the Santa Rosa, Nix, Medical Arts, Physicians and Surgeons and Medical and Surgical Memorial hospitals; consulting surgeon at the Robert B. Green Memorial Hospital; died in the Touro Infirmary, New Orleans, June 15, aged 60.

Herman Schwarz ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1898; served on the faculty of his alma mater; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; director of the department of pediatrics, serving as president of the medical board, Beth Israel Hospital; for many years associated with Mount Sinai Hospital, serving on the staff as consulting pediatrician at the time of his death; died in Bedford Village, N. Y., May 19, aged 69, of coronary thrombosis.

Eleanor Holden Balph ⊕ Philadelphia; University of Pittsburgh School of Medicine, 1918; clinical assistant professor of gynecology at the Woman's Medical College of Pennsylvania; member of the Philadelphia Obstetrical Society; fellow of the American College of Surgeons; interned at the Hospital of the Woman's Medical College of Pennsylvania; chief of gynecology at the Woman's Hospital, where she died May 21, aged 57.

Annetta E. Barber, Glens Falls, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1898; retired member of the Medical Society of the State of New York and member of the American Medical Association; died April 26, aged 86.

Foster Flavorial Burnett, Wilmington, N. C.; Howard University College of Medicine, Washington, D. C., 1917; served during World War I; an examining physician for city draft board number 1; a founder of the Community Hospital, where he died May 31, aged 54, of pulmonary embolism and chronic leukemia.

John William Patton, Cabool, Mo.; University of Maryland School of Medicine, Baltimore, 1886; served on the staffs of the North Dakota State Hospital for Insane, Jamestown, and the Toledo State Hospital in Toledo, Ohio; died March 17, aged 84, of ascites and cerebral hemorrhage.

James L. Prine, Day, Fla.; University of Georgia Medical Department, Augusta, 1900; died March 6, aged 71.

CAPT. TRUMBULL FRAZER
M. C., A. U. S., 1915-1945

LIEUT. WILLIAM H. MILLMANN
M. C., A. U. S., 1918-1945

LIEUT. (JG) ROBERT SMITH NICHOLS
(MC), U.S.N.R., 1920-1945

KILLED IN ACTION

Trumbull Frazer, Asheville, N. C.; Cornell University Medical College, New York, 1942; diplomate of the National Board of Medical Examiners; interned at the Rhode Island Hospital in Providence; served a residency at the Massachusetts Eye and Ear Infirmary in Boston and the Station Hospital, U. S. Army, Biggs Field, El Paso, Texas; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 30, 1943; later promoted to captain; killed in action in Germany February 7, aged 29.

William Henry Millmann, Shorewood, Wis.; Marquette University School of Medicine, Milwaukee, 1943; interned at St. Mary's Hospital in Milwaukee; entered the medical corps of the Army of the United States as a first lieutenant on Oct. 18, 1943; began active duty on Aug. 4, 1944; killed in action in Italy February 21, aged 26.

Robert Smith Nichols, Hanover, N. H.; University of Pennsylvania School of Medicine, Philadelphia, 1943; diplomate of the National Board of Medical Examiners; interned at the Hospital of the University of Pennsylvania in Philadelphia; began active duty as a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on Nov. 14, 1944; assigned to Navy Yard in Philadelphia; killed in action on Okinawa April 1, aged 24, while attempting to give aid to a wounded hospital corpsman.

MARIHUANA PROBLEMS

To the Editor:—In an editorial (THE JOURNAL, April 28, p. 1129) appears a criticism of a report on marihuana by the New York City Mayor's Committee on Marihuana.

The editorial states "Nevertheless, a book called 'Marihuana Problems' by the New York City Mayor's Committee on Marihuana submits an analysis by seventeen doctors of tests on 77 prisoners and, on this narrow and thoroughly unscientific foundation, draws sweeping and inadequate conclusions which *minimize the harmfulness of marihuana.*"

The report was not an analysis by seventeen doctors of 77 prisoners. The Mayor's committee did not even consist of seventeen doctors of medicine; and if the writer of the editorial had read the report carefully he would have noted that only sixteen different names are given as comprising the Mayor's committee and that two of these are not M.D.'s. Nor were there 77 prisoners studied. Of the 77 persons studied 5 were volunteers, not prisoners. This is clearly stated in the text.

Any one reading the editorial would not realize that Mayor La Guardia "sought advice from the New York Academy of Medicine"; and, as he states in the foreword, "On the academy's recommendation I appointed a special committee to make a thorough sociological and scientific investigation and secured funds from three foundations with which to finance these studies." The New York Academy of Medicine kept in close touch and advised concerning the study throughout the entire period during which it was carried out.

The study was actually carried out as follows: Two subcommittees were appointed, one to plan a sociological study, the other to work out details of the clinical study. The sociological study was carried out under the active direction of Dr. Dudley D. Shoenfeld, using six police officers who had been specially trained as social investigators. The Police Department placed the services of the Narcotic Squad Division at the disposal of the Mayor's committee. Six members, four men and two women, carried out for a period of over one year a painstaking investigation of the use of marihuana in the city of New York.

The report states that in this period of over a year "while on duty, the squad actually lived in the environment in which marihuana smoking or peddling was suspected. They frequented poolrooms, bars and grills. . . . They consorted with habitués of these places. . . . They posed as suckers from out of town and as students in colleges and high schools." From this sociological study and not simply from tests of 77 (actually 72) prisoners, as stated in the editorial, thirteen conclusions were drawn, the following of which are quoted:

7. The practice of smoking marihuana does not lead to addiction in the medical sense of the word.

10. Marihuana is not the determining factor in the commission of major crimes.

13. The publicity concerning the catastrophic effects of marihuana smoking in New York City is unfounded.

The editorial states that "the report states that the relation between marihuana and crime is unfounded. This opinion, based on tests of 77 prisoners, denies much available evidence." Since, as has just been shown, the report describes conditions in New York City and concludes that there is no important relationship between marihuana and crime in that city, and since these conclusions are not based on "tests of 77 prisoners," it is apparent that the writer of the editorial has either not read the report carefully or is deliberately misrepresenting the facts.

Besides the sociological study, clinical studies including medical aspects, psychologic aspects and pharmacologic aspects are reported. The pharmacologic study takes up sixty-four pages of the report and includes much valuable material as to the active principle of marihuana and gives actual experimental work with animals. The psychologic studies, which were most carefully done, include the use of a large number of the standard types of tests and some of the newer technics, such as play technic.

The conclusions as written by Dr. Wallace, chairman of the committee, are that the first phase of the study, namely the sociological, indicates that "the marihuana user does not come from the hardened criminal class, and there was found no direct relationship between the commission of crimes of violence and marihuana." He then goes on to state that under the clinical study "in a limited number of the subjects there were alterations in behavior giving rise to antisocial expression. This was shown by unconventional acts not permitted in public, anxiety reactions, opposition and antagonism, and eroticism. Effects such as these would be considered conducive to acts of violence. However, any tendency toward violence was expressed verbally and not by physical actions, and in no case was restraint by force needed." These, then, were some of the conclusions drawn from the study of 72 confined criminals and 5 volunteers. They are not what one would assume to be the case in reading the editorial in THE JOURNAL.

The editorial then goes on, "Kolb, nationally known addiction expert, after reading the report stated 'one may say of such a drug that, if it were abused as alcohol is abused, it might be an important cause of crimes and other misdemeanors.'" The report of the Mayor's committee was published in the latter part of 1944. The quotation from Dr. Lawrence Kolb appears in the discussion of a paper read at the meeting of the American Psychiatric Association at Boston, May 18 to 21, 1942. At least one presumes that the quotation intended is the following: "It can readily be seen that a drug which produces all these effects, if used as widely as alcohol is used in this country, might be like alcohol a very important contributing cause to crimes of various kinds."

Kolb's discussion occupies a considerable part of a whole page, the quotation being from page 251 of volume 99, number 2, September 1942, of the *American Journal of Psychiatry.* One wonders why the writer of the editorial left out the following portion of Kolb's statement, which would certainly give the readers of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION an entirely different idea of the dangers of marihuana than the partial and garbled quotation. I quote as follows: "In view of the misinformation and alarm that has gotten abroad about marihuana it is important to have a competent group like the Mayor's committee to study this drug and present the real facts. *In the meantime* [italics mine], Dr. Allentuck's timely paper will tend at least to get physicians' feet back on the ground. The case against marihuana has been very much overdrawn, but we learn from Dr. Allentuck that the drug does have intoxicating effects and that in susceptible people it may precipitate a psychosis. A drug which has these properties is, of course, dangerous. . . . The studies should be made if possible in a country such as Mexico where there is said to be a really widespread use of marihuana. It is of interest, however, that many physicians in Mexico feel that marihuana does little if any harm. It is reassuring to find from the careful study that Dr. Allentuck has made that the alarm about the relation of marihuana to crime is unfounded. The drug, like most other intoxicants, is taken mostly because it produces a sense of ease and finally sleep, but on its way to this final result there is a peculiar, bizarre type of intoxication with release of inhibitions."

The editorial further states that "the report proposes the use of marihuana in the treatment of drug addiction and chronic alcoholism. Bouquet, the League of Nations expert, and others agree with Kolb that this proposal enters dangerous territory and that the result can only be the substitution of one addiction for another." On page 218 of the Report of the Mayor's Committee, under "Summary," appears the following statement: "From limited observations on addicts undergoing morphine

withdrawal and on certain types of psychopathic disturbances, the impression was gained that marihuana had beneficial effects, but much more extensive and controlled study is required for definite conclusions to be drawn concerning therapeutic usage." Likewise, on page 148 under chapter "Possible Therapeutic Applications" it is also stated "However, the studies here described were not sufficiently complete to establish the value of such treatment, and before conclusions can be drawn the problem must be investigated under completely controlled conditions."

Do these sound like "sweeping and inadequate conclusions" on "narrow and thoroughly unscientific foundations"? Or does this not seem like the type of conclusions which careful, scientific observers give after a study which they feel does not warrant final conclusions?

There have been further studies made in New York City on the relationship of marihuana to crime, and the psychiatric examination of convicted prisoners at the Court of General Sessions and the studies of persons charged with crime made in the prison wards of the psychiatric division of Bellevue Hospital confirm that marihuana is not an important cause of crimes of violence in New York City.

The claim in the editorial that "the recent article which appeared in the December 1944 issue of *War Medicine* entitled 'The Marihuana Addict in the Army,' by Captain Eli Marcovitz and Captain Henry J. Myers, is a devastating refutation of the information contained in the La Guardia report" is hardly borne out by a careful study of the article. On page 4 it is stated that "marihuana addicts usually present an extremely complex picture in which the use of the drug is but one aspect." Under "Summary and Conclusions" on page 9 it states that, "as a group, their backgrounds were heavily loaded with adverse familial, social and economic factors. Their histories were characterized by delinquent and criminal behavior and failure to develop any consistent patterns of productive work." It is also stated "Our experience indicates that a confirmed marihuana addict of the type described here is a sick personality whose maladjustment has been determined not only by his own personality and character patterns but by adverse socioeconomic factors."

It is also pointed out in their study that "it must be emphasized that our conclusions are based on observations of a specialized group of marihuana addicts, namely a group in military service with difficulties which brought them to the attention of the military or medical authorities. Undoubtedly there are other types of marihuana users or even addicts (e. g., band musicians), observation of whom might lead to somewhat different conclusions."

Many persons fail to differentiate between cause and effect. Marihuana is often used by inadequate and maladjusted individuals who were this way long before they started the use of marihuana. It is also used by many unstable psychopaths, and acute psychotic episodes may be precipitated in these individuals by its use. The conclusion that they are maladjusted because of the use of marihuana is only a partial truth. The use of any narcotizing drug, as marihuana, alcohol or opium, contributes to further maladjustment, but the fundamental personality defect and the original maladjustment are the important problems and the marihuana is much more a symptom than a cause.

The report describes conditions in New York City, gives details of careful medical, psychiatric and psychologic tests on 5 volunteers and 72 prisoners and of special pharmacologic studies. As a result of the sociological studies certain conclusions were drawn about the use of marihuana and its relation to crime in New York City. From the other studies certain conclusions were drawn, and in certain instances it was pointed out that further studies were necessary before any decision could be made.

KARL M. BOWMAN, M.D., San Francisco.

BLOOD BANK OF QUEENS COUNTY, INC.

To the Editor:—Supplementing my communication in THE JOURNAL, May 19, I wish to call attention to the results obtained at the Mary Immaculate Hospital, adjacent to the Blood Bank of Queens County, as submitted to me by the obstetric department. Excepting one death from a brain tumor and one from pneumonia, there was not a maternal death for a period of one year. There were 1,736 deliveries. This was due in part to having blood of the proper type and Rh factor available at the moment the patient entered the delivery room.

When the obstetrician draws blood for a Wassermann test in the early stages of pregnancy he also determines the type and Rh factor of the patient and on admission to the hospital blood of her type and Rh factor is placed in an ice box adjacent to the delivery room in case of need. Blood of all types is easily kept through the cooperation of both doctor and hospital insisting that relatives or friends replace on a two for one basis. Persons paying for their hospitalization in 80 per cent of the cases have blood on deposit in advance. The uncooperative 20 per cent are asked to make a cash deposit equivalent to the cost of a professional donor. In our plan it is $35, which is returned to them on replacement.

Blood may be obtained at varying prices, as low as $15, but the replacements are so few, owing to the small deposit required, that it is necessary for suppliers to solicit random donors for a fee, usually $5. When the deposit is kept at the higher level, it is unnecessary to solicit donors and we always have more blood than we need, even for all the free cases, and no one is denied blood regardless of ability to pay or replace. Four out of five of the few who do put up the deposit come in during the ninety day period allowed for replacement and obtain their refund.

The identification card for blood donors as described in THE JOURNAL of May 19 has created great interest in mutual blood donor groups, especially among Rh negatives.

EDWARD J. MADDEN, Jamaica, N. Y.
Chairman, Blood Bank of Queens County.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, July 14, page 826.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* San Francisco, Oct. 15-17. *Written.* Various centers, Oct. 15. Final date for filing application is Aug. 1. Candidates in the armed forces may take the examination at their station with the permission of their medical commanding officer. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison 5, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, May 27. Final date for filing application is Jan. 31. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 4-6; and Los Angeles, January. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part I. Oral and Written.* New Orleans, Sept. 28-29, Philadelphia, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Oct. 19. *Oral.* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Oral.* Fall, 1945. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various centers, October 24. Final date for filing application is Aug. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY: *Written.* Chicago, Dec. 9. *Oral.* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

MEDICOLEGAL ABSTRACTS

Requirement of Maine Nurses Registration Act That Applicant for Registration Be Graduate of Nursing School Presided over by Maine Registrant Valid.—The nurses registration act of Maine provides for the registration and certification of professional trained nurses and that a register of their names be open at all times to public scrutiny. The administration of the act is committed to a Board of Registration of Nurses. Registration is purely voluntary and in no way compulsory. Any nurse possessing the qualifications required in the act may submit to examination for registration. Nurses who are registered in other states are entitled to registration without examination. While the practice of professional nursing as a registered nurse without a certificate of registration is prohibited, the act expressly states that it does not apply to the nursing of the sick by any person who does not represent himself or herself to be a registered nurse. One section of the act authorizes the board to admit to examination for registration any applicant who possesses stated qualifications, among which is the completion of a course of not less than two years in a school of nursing approved by the board "and presided over by a nurse registered in accordance with the requirements" of the act. Irene Snelson, who apparently possessed all the qualifications required by the act except that she had not graduated from a school of nursing presided over by a nurse registered under the Maine act, sought to be examined for registration under the Maine act. The board refused to examine her and she subsequently sought a writ of mandamus for admission to examination for registration as a registered nurse, alleging that she was eligible for registration and that the refusal of the board to admit her to examination was illegal and a violation of her constitutional rights. In effect, there was a judgment in favor of Irene Snelson and the board appealed to the Supreme Judicial Court of Maine.

The purpose of the nurses registration act of Maine, said the court, relating to the registration and certification of registered nurses is not to regulate or control the practice of nursing as a calling but to designate by public registry and certification those nurses for whose qualifications the state is willing to vouch and to prevent others who are not entitled to it from claiming falsely such sponsorship Under the act no applicant for registration and certification as a registered nurse can be admitted to examination unless he or she has complied with all the conditions there enumerated and one of those conditions is that the applicant for examination for registration shall have been trained in an approved school of nursing presided over by a nurse registered in Maine. This requirement applies alike to nursing schools in Maine and to nursing schools situated outside the state. The language of that provision is clear and unambiguous, and its operation cannot be limited or extended by reading into it a meaning at variance with its express terms. Regardless of the standing of the nursing school at which the applicant had studied or the reasons why the school had not been approved, the fact that it was neither approved nor presided over by the act in question compelled the board to refuse to admit her to examination. The board cannot be required by a mandamus to violate its duty and to disobey the law.

On the record before us it is unnecessary, continued the court, to pass on the contention that that portion of the act is unconstitutional that requires an applicant for admission to examination to have been trained in an approved school of nursing presided over by a nurse registered in Maine. That provision is an integral part of the nurses registration act, and if that provision is void the act in its entirety is a nullity and registration and certification of registered nurses by examination has no sanction in law and a right to registration would therefore not exist in the state. On a premise of the unconstitutionality of the act authorizing the registration and certification of registered nurses by examination a writ of mandamus could not be issued commanding the performance of an act by the board which it had no power to perform. The validity of a statute cannot be assailed if the benefits of that statute are invoked in the same proceeding.

The court accordingly held that the board acted properly in refusing to admit Irene Snelson to examination for registration as a registered nurse—*Snelson v. Culton et al., Board of Registration of Nurses, 42 A. (2d) 505 (Maine, 1945).*

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D. D. N. J. and foods, F. N. J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Delayed Menstruation Tablets and Herb Tea.—Bernard McBrady, trading as J. E. McBrady & Company, Chicago Shipped July 28 and 29 and Dec 12, 1941. Composition: Delayed Menstruation Tablets contained iron sulfate, extracts of plant drugs, including aloe, and an alkaloid bearing drug, with oil of savin, and coating of red calcium carbonate, Herb Tea No 104, chiefly a mixture of senna leaves, camomile, cascara sagrada, elder flowers, dill seed, caraway, American saffron, uva ursi, licorice root, peppermint and sassafras, Herb Tea No. 107, senna leaves and pods, uva ursi, camomile flowers, rosemary leaves, sage leaves, comfrey root, oak bark, sweet orange peel, unicorn root, condurango bark, peppermint leaves and gentian root; Herb Tea No. 109, essentially a mixture of senna leaves and pods, cinchona bark, sweet orange peel, comfrey root, red clover tops, sassafras bark and sarsaparilla root; Herb Tea No. 110, essentially senna pods, malva flowers, horehound, tansy herb, camomile flowers, comfrey root, cinchona bark, ruta herb and sage; Herb Tea No 114, chiefly marshmallow root, coltsfoot leaves, licorice root, mullein leaves, broom tops and linden flowers, Herb Tea *No. 124, essentially* leaves of spearmint, uva ursi and witch hazel, with hops, camomile flowers, red oak bark and unidentified plant material Delayed Menstruation Tablets misbranded because of false implication in the name and the label claim, "For Painful, Suppressed, Profuse or delayed by Colds" Herb Tea No 104 misbranded because represented to prevent or correct indigestion, poor appetite, sluggishness and some other things, and to save health and prolong life Herb Tea No. 107 misbranded because falsely represented in labeling as a cure or preventive of leucorrhea. Herb Tea No 109 misbranded because label falsely represented it as efficacious for skin eruptions. Herb Tea No 110 misbranded because of misleading label representation that it was effective in delayed menstruation. Herb Tea No 114 misbranded because labeling represented product as an effective treatment for irritating cough, minor chest colds and pains Herb Tea No 124 misbranded because it was not a cure or effective treatment or preventive of sores and ulcers—[*D D N. J., F. D. C. 887, May 1944*]

Sill's Powder Treatment and Sill's Powder Foot Treatment.—Sills Company, Vinita, Okla Shipped Feb 17 and March 27, 1942. Composition of both products identical, consisting essentially of salicylic acid, small amounts of bismuth subcarbonate, ammonium alum, boric acid, and aspirin in a base of talc Misbranded because falsely represented in labeling as an effective treatment for many foot and general skin disorders—[*D. D. N. J., F. D. C. 892; May 1944*]

VeDor No. 578 Injection.—Primrose R Devore, trading as Drug Products Company, Columbus, Ohio Shipped June 18 and Sept. 4, 1941. Composition: essentially small amounts of zinc sulfate and lead acetate in water. Misbranded because statement "Use in connection with Anti-Gon Internal No. 578" falsely implied that the product constituted part of a treatment for gonorrhea and that, when used in connection with the one named, it would be efficacious in treating that condition, whereas it had no value either alone or in conjunction with the other mixture in such treatment. Also misbranded in that label failed to give the common name of each active ingredient, inasmuch as zinc sulfate was not declared Misbranded, further, because label did not bear an adequate statement of the quantity of the contents—[*D. D N. J., F. D. C. 884; May 1944*]

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for *permanent possession only from them.*

Relation of Respiratory Allergy to Unresolved Pneumonia J. A. Turnbull—p 176

Appetite and Obesity.—Hoelzel asserts that all normal rats will eat enough to become fat if enough palatable and highly nutritious food is available. Uninhibited, normal human beings will apparently do likewise. Apart from this, appetite is likely to become excessive when hydration becomes abnormally increased, either because of the type of diet used or because of the amount of food eaten or as a result of endocrine factors (as in menstrual edema and hydration associated with pregnancy) or after recovery from disease. Appetite can best be controlled by keeping hydration within normal bounds

Sugar Metabolism After Subtotal Gastrectomy.—In 14 patients who had undergone subtotal gastrectomy, Glaessner found that even oral intake of 100 Gm. of glucose provoked characteristic attacks of hyperglycemic shock consisting of manifestations of nausea, vomiting, headache, cramps in the abdomen, coma and nystagmus. These attacks are probably caused by a sudden rise of blood sugar. Studies during hyperglycemic shock revealed disorders of the vascular system such as increase of the pulse rate and decrease of the systolic and especially of the diastolic blood pressure. In a few cases a comatose condition could be observed · disorientation and soft eyeballs

Clinical Survey of 125 Cases of Infection with Ascaris Lumbricoides in Children N H. Einhorn, J F Miller and L Whittier—p 237.

Flora of Upper Respiratory Tract of Newborn Infants.—Torrey and Reese made cultures of material from the throats and the noses of 105 full term infants during the first twenty-four hours after birth No bacterial growth was obtained from swabbings of those regions taken within four hours after birth in 95 per cent of the group so studied. This result confirms the conclusion of a previous study that normally the initial flora of the nose and throat is acquired mainly from the environment after birth and not from the parturient canal Cultures of material from infants 13 to 18 hours old indicated continued sterility of the nose in 31 per cent and of the throat in 4 per cent, but by the end of the first day the cultures of all infants examined yielded growth from both regions. White staphylococci, alpha or gamma streptococci and, less frequently, diphtheroids were the first organisms to invade the oral cavity. The upper respiratory tract during the first two weeks of life rarely becomes infected with the pneumococcus, the beta hemolytic streptococcus, Hemophilus influenzae and the Friedlander bacillus through contact with nursing mothers who are carriers of these organisms. Although occasionally the pneumococcus was cultured from the nasopharynx within a few days of birth, it soon disappeared from the secretions. The mucous membrane of this region of the newborn infant is unreceptive not only to these pathogens but to certain other bacterial types, such as Streptococcus salivarius, the gram-negative diplococci and the hemoglobinophilic Hemophilus hemolyticus, which thrive there later in life. If acquired, these organisms are also soon eliminated. Routine use of the conventional types of face masks by persons in contact with the infants is of little value in preventing the acquisition by the newborn infant of organisms of the respiratory tract, pathogenic or otherwise.

Penicillin Therapy of Rat Bite Fevers.—Twenty-five cases of rat bite were treated at the Children's Hospital of Michigan during 1944. One child died of pneumonia after extensive rat bites but without clinical signs characteristic of rat bite fever. Five others had rat bite fever. Spirillum moniliformis was isolated from the blood stream of 4 of these children and Spirillum minus from that of 1 child One of the children with infection due to S. moniliformis died of diarrhea and jaundice after having had one dose of oxophenarsine hydrochloride. The remaining patients were treated with penicillin and had prompt and dramatic recovery. A dose of 5,000 units of penicillin given intramuscularly every two to three hours for a week to ten days seemed adequate to control both types of infection in these babies, who weighed from 5 to 12 pounds (2 3 to 5 4 Kg.). Wheeler has found that it has been possible to isolate and cultivate Streptobacillus moniliformis easily, using only the mediums and equipment which are routinely employed in the laboratories of most children's hospitals.

*Severe Light Hypersensitiveness Cured by Cholecystectomy. E Urbach and H. Shay.—p. 124

Hypersensitiveness to Light Cured by Cholecystectomy.—A woman aged 63 had a severe light dermatosis, which was cured by extirpation of the infected gallbladder. As in other cases of light hypersensitiveness, a pathologic intestinal flora was found. This may well have been the cause of the increased porphyrin content of the stool. Two possible mechanisms are suggested by Urbach and Shay through either of which the diseased gallbladder might have been responsible for the agent causing the hypersensitiveness to light.

Skin Grafts from Neck for Eyelid and Face Repairs.—Brown and Cannon say that full thickness grafts from the neck and the clavicular region have been found to give superior results in the repair of facial defects. The amount of skin available is limited, but there is enough for the eyelids, for the nose and about the mouth. The color is nearly always close to that of the normal face. None of these grafts so far have had to have pigment injection for color matching, whereas dead whiteness or darkness of other grafts often leaves much to be desired. The second advantage is softness and therefore function. These grafts heal and have such thickness that the best kinesis of grafted areas can develop This property is best expressed in eyelid repairs, where hard, boardlike scars of gasoline and phosphorus burns have to be literally dug out of the lids and across from one eye to the other over the nose When these areas are covered with the neck grafts there is often a dramatic relief of scar fixation and return of softness and function. The main areas for use are on the lids, in the canthal regions, about the ala, over the nose and about the lips and angles of the mouth. As a rule, flap repairs are considered for gunshot wounds, whereas grafts usually suffice for burns. However, about the lids, if a bed at all suitable can be obtained by dissection of the scars, these full thickness grafts are used in preference to flaps and, it is thought, with better results. Donor sites can be closed, left open to granulate or grafted. They may make troublesome scars for a while, but no permanent severe trouble has been seen.

Prophylaxis of Wound Infection.—A series of experiments performed by Peterson on animals indicated the efficacy of the various soaps as germicidal agents. When the soaps were placed in actual contact with the uncontaminated fresh wounds they produced a definite but slight irritation. This was noted only on microscopic examination; gross examination revealed no difference between control wounds and wounds into which soap had been placed. In wounds which were contaminated by placing a given amount of a culture of Staphylococcus aureus within their depths and then exposed to soap there was a definite increase in signs of infection over those found in the control wounds not exposed to soap; "green" soap was found more irritating than "white" soap. The harmful effect of mechanical washing of wounds is in direct proportion to the coarseness of the material used. Of the various methods studied the cleansing of contaminated wounds by a gentle irrigation with isotonic solution of sodium chloride is the most effective prophylaxis of wound infection Contaminated wounds treated with this gentle irrigation healed with less evidence of infection than did control contaminated wounds subjected to no treatment other than closure at the specified time. Best results in cleansing small wounds were obtained by irrigating them with 1,000 cc. of saline solution with no scrubbing, utilizing the force of the stream as the washing mechanism.

Blood Iodine.—Curtis and Fertman made a comparative analysis of the blood iodine, basal metabolic rate and certain other factors in 138 different clinical conditions in a total of 818 persons. In the years between 1932 and 1936 they determined the blood iodine by the dry ash technic, from 1936 to date by the chromium trioxide method. The average blood iodine level was found to be significantly elevated in all forms of toxic goiter. Associated with the increase in the blood iodine there occurred an elevated average basal metabolic rate. In no two groups of toxic goiter, including the exophthalmic variety, was there found by statistical test any significant difference between the average blood iodine concentrations. Some difference in the nature or quantity of the whole or fractionated blood iodine might be expected in exophthalmic goiter and should be further investigated The blood iodine may rise as high in toxic nodular goiter as in exophthalmic goiter. The average blood iodine level was not significantly elevated in nontoxic nodular goiter and in nontoxic diffuse colloid goiter. The average basal metabolic rate was significantly increased in nontoxic nodular goiter but averaged only minus 7 per cent

in diffuse nontoxic colloid goiter. The average blood iodine in 79 patients with hypothyroidism was not significantly lower than that in normal persons from this goitrous region, although the average basal metabolic rate was reduced. The average blood iodine in 9 patients with carcinoma of the thyroid, unlike that of a previous group of 3 similar patients, did not differ significantly from the normal in spite of an elevated basal metabolic rate. There was no significant correlation between the blood iodine level and the duration of the symptoms due to the carcinoma or to those of goiter when such was recorded. It would appear that the level of the blood iodine in carcinoma of the thyroid is more dependent on the nature of the thyroid gland in which the malignant growth occurs than on the malignant growth itself. In none of the thyroid disorders investigated was there any significant linear correlation between the level of the blood iodine and the duration of symptoms or of goiter. That some association may exist was indicated by a significant positive multiple correlation coefficient of the blood iodine in relation to the basal metabolic rate and the duration of toxic symptoms in hyperthyroidism or of goiter in nontoxic nodular goiter. This relationship shows that the blood iodine increases rather than decreases with some combination of the other two factors. In 3 patients with chronic thyroiditis the average blood iodine was not significantly elevated.

Technic for Staining Malaria Smears. D. A. Boroff and R. W. Gronemyer.—p. 113.

Reactions to Typhus Vaccine.—Roth states that constitutional or allergic reactions may occur following injections of typhus vaccine. Four of 9 patients with allergic reactions gave a history of egg allergy. Available evidence indicates that allergic reactions are caused by some residual egg allergen in the vaccine. To avoid serious and possibly fatal reactions, precautions should be the same as those taken before injecting horse serum products.

*Phantom Limb Syndrome: Discussion of Role of Major Peripheral Nerve Neuromas. K. E. Livingston.—p. 251.

Peripheral Nerve Injury After Fractures.—The 53 nerve injuries for which Gurdjian and Smathers performed operations included 32 radial, 9 ulnar, 3 median, 8 peroneal and 1 sciatic nerve. The work was done mainly at the Receiving and Grace hospitals in Detroit. Early exploration in cases of nerve lesion associated with fracture of long bones is justifiable after complete study of the history, physical findings and x-ray films. If, from an orthopedic standpoint, open reduction is a procedure of choice, the involved nerve can be explored at the same time. Early exploration in ulnar nerve palsy associated with fracture of the medial condyle of the humerus is preferable. Anterior transposition of the nerve may then be carried out. Early exploration of primary peroneal palsy is desirable in injuries of the knee joint with fracture of the upper end of the fibula. There is a great likelihood of a torn nerve in most cases of primary peroneal palsy with fracture of the upper end of the fibula. In fractures of the middle third of the humerus complicated with radial palsy, exploration in eight to ten weeks is justifiable if there are no evidences of returning function. In compound fractures associated with nerve lesions early repair is feasible, particularly with present day chemotherapeutic measures. A nerve should be explored if there is no evidence of regeneration three to four months after a fracture of the neighboring bone.

Phantom Limb Syndrome.—Forty-two patients with a total of 50 major extremity amputations were studied in detail. Of the 50 amputations only 1 was never associated with phantom limb symptoms. The phantom limb is not a total reproduction of the amputated extremity. In upper extremity amputations the fingers are most prominent. The palm is less frequently felt, and the wrist and dorsum of the hand are usually not present. The forearm and upper arm are rarely perceived. Many patients give the impression that they feel "the whole thing," but on careful questioning it is evident that the posture and presence of much of the phantom limb are inferred often from small portions of the hand or fingers of which the patient has specific impressions. In lower extremity amputations similar phantom patterning is found. In neither extremity does the pattern correspond to the major peripheral nerve distributions. A majority of these patients felt that their phantom limbs had been clearly established immediately or very soon after amputation. The neuroma is not established early enough to be the determining factor in these initial symptoms. In 14 of these patients with 20 amputated limbs a total of 30 major nerve neuromas were accessible. On vigorous palpation of the neuroma, most of the patients described their sensation as like "striking your funny-bone." In no case did stimulation of the neuroma excite or simulate typical phantom sensations. Livingston thinks that the high incidence of phantom limb impression following amputation, its early appearance and its stability suggest a central rather than a peripheral denominator for these symptoms. The occurrence and persistence of severe phantom limb pain in a comparatively small proportion of the patients with phantom limb symptoms suggest an irritative disturbance that is superimposed on the underlying phantom limb mechanism. Evidence from these observations and from clinical experience suggests that the major peripheral nerve neuroma is rarely the "key" factor in this irritative process.

Nutrition of Patients with Thermal Burns.—Levenson and his associates say that with the increased use of plasma and the reemphasis of the proper use of electrolyte solutions many of the severely burned patients who formerly died of circulatory collapse are being brought through the early shock phase into the later period frequently characterized by nutritional disturbances. Thus the problem of malnutrition following thermal injury must now be faced in an increasing number of patients. The authors report 32 cases in which an effort was made to determine the protein and caloric requirements. The nutritional disturbances and especially the increased demand for protein was found to be directly related to the extent of the third degree burn. High caloric, high vitamin diets with up to 400 Gm. of protein per day were necessary in some cases. When this quantity of food could not be taken or tolerated, gavage and intravenous supplements were given. In cases in which nutritional requirements were not met, malnutrition developed, skin grafting and healing were delayed and, frequently, death ensued.

Absorbable Oxidized Cellulose with Thrombin as Hemostatic Agent.—Absorbable oxidized cellulose is prepared in the form of a transparent gauzelike material and a heavier material that resembles absorbent cotton. The material placed in individual sterile envelops cannot be reautoclaved, since it disintegrates. It may be boiled three minutes or kept in 70 per cent alcohol until used. The manufacturer also supplies concentrated dried thrombin in ampules containing either 5,000 or 10,000 units. The thrombin should be dissolved in no more than 5 cc. of a sterile saline solution. Absorbable oxidized cellulose, either gauzelike or cottonlike in type, with a solution of thrombin, was tried by surgeons of the Mayo Clinic as an aid to hemostasis in 60 cases. Results were encouraging; hemostasis was excellent and immediate in 37 cases and satisfactory in 20 cases. The hemostatic effect of oxidized cellulose seems to depend on its sticky character when saturated with blood. It produces minimum tissue reaction and is relatively nonirritating and readily absorbable. It can be removed from a wound without the secondary bleeding that so frequently occurs after removal of ordinary gauze. Since cellulose is a foreign body, however, use of a large amount of it in a deep, nondrained wound may be unwise. In pathologic studies no fibers were found remaining in the tissues four and one-half days after the material had been introduced into the wound.

Diagnosis of Bone Tumors by Aspiration Biopsy.—Snyder and Coley survey 567 bone aspirations done on 474 patients during the last twelve years. There have been no immediate complications of the procedure and no evidence to suggest more rapid development of metastasis. In primary bone tumors and metastatic carcinoma of bone, aspiration has been done in 385 cases, of which 67.5 per cent were definitely and specifically diagnostic, while a total of 82 per cent showed material sufficient for the diagnosis of tumor, the exact type diagnosis not being called in 14.5 per cent. In only 1 instance was a diagnosis of malignant tumor made when the resected specimen showed a benign tumor and in this case the treatment was local resection. Thus in no case did a false aspiration diagnosis lead to amputation for a benign process. The clinician must understand the scope and limitations of the method and realize that failure to obtain cells means only that no tissue was obtained, further interpretation depending on the clinical and roentgenographic findings. Aspiration biopsy has proved itself to be a valuable and reliable diagnostic procedure.

Pulmonary Concussion in Nonthoracic Battle Wounds.—Savage performed complete necropsies on 87 battle casualties who had died mostly of various types of head wounds, spinal wounds, burns and the like. In 30 of these there were lung changes which were considered to be due to blast. In the earlier cases there was no evidence before death that the lungs were affected, but later in the series, when routine chest x-ray films were taken in patients who might have been exposed to blast, the typical radiologic changes were sometimes found. The time between wounding and death varied from under an hour to eighty-three days. The surfaces of the lungs generally showed no change, but when sectioned a striking "spatter" of hemorrhages was seen. In some, these had coalesced to form areas of consolidation. To obtain a record of the distribution of the hemorrhages, many of these lungs were reinflated at necropsy and x-rayed. Two types of picture were seen: (1) scattered opacities, sometimes confined to one lobe, and (2) the same scattered opacities, but in parts with hemorrhages so numerous that an appearance of consolidation was given. Evidence of blast hemorrhage elsewhere in the body was seen ten times. The liver was found bruised in 6 patients. Hemorrhages on the surface of the heart were seen four times. Small areas of hemorrhage were seen in the pancreas, spleen and colon, each on 1 occasion. In 23 of the 30 cases showing lung hemorrhages it was certain that they had been exposed to blast; in the remaining 7 the method of wounding was unknown.

Placental Globulin Extract for Measles.—According to Chu and Liu a dry form of placental globulin extract may be prepared by means of methyl alcohol precipitation. It has the advantage over the usual wet product, as prepared by ammonium sulfate precipitation, in that it is convenient for pooling and storage without deterioration. When the dry product is redissolved and sterilized by the addition of merthiolate, it is ready for intramuscular injection for measles prophylaxis. The protein content of the solution should be determined for the calculation of doses. Ninety children who had been exposed to measles in families and orphanages were passively immunized by this placental extract. Either modification or prevention of the disease could be accomplished. Mild and general reactions were observed in 54 and 33 cases respectively. An attempt was made to standardize the dosage. It was found that the range of doses effective for modification was overlapped on the one hand by the range for complete prevention and on the other hand by that producing no effect at all. A dose of 25 to 30 mg. per kilogram of body weight for the fourth to sixth day of exposure or of 40 to 45 mg. per kilogram for the seventh to ninth day is very likely to result in the modification of the disease. Complete protection can be expected if a dose of more than 40 mg. per kilogram is used in the early incubation period.

Congenital Malaria.—According to Chen and his associates it has been amply proved that malaria can be transmitted through the placenta. They give a tabulated report of 39 cases which they collected from the literature and also present an observation of their own concerning a male infant whose mother had an attack of chills and fever when labor pains began. Two days later she had another bout of chills and fever, and tertian malarial parasites were found in the blood. On examination of the infant about seven weeks after birth the mother stated that he had been pale and losing weight since birth and that he had nursed poorly during the week prior to admission. The blood was found to have a hemoglobin content of only 10 per cent and an erythrocyte count of 1,060,000. Gametocytes of tertian malaria were found in the peripheral blood. It is believed that this is a case of congenital malaria. The history is suggestive. The mother had repeated attacks of malaria throughout the period of gestation and finally the infant was delivered during one such attack. The extreme degree of anemia cannot be explained on any other basis. The enlarged liver and spleen are presumably due to malaria. Finally the finding of the tertian malarial parasites in the peripheral blood is diagnostic and conclusive. The child responded splendidly to blood transfusion. Unfortunately an infection of the meninges interrupted the course of illness. Quinine was given but there was not enough time to determine its effect before the patient succumbed to the complication. The time of year, December-January, makes a postnatal infection unlikely.

Hereditary Damage by Roentgen Rays.—Fick's patient was a woman aged 28 with peritoneal tuberculosis. The family history of the woman as well as that of her husband did not reveal any hereditary disease. Four applications of roentgen rays with a total dosage of 350 roentgens were applied to the hypogastrium of the patient. This treatment was erroneously considered responsible for the amenorrhea occurring after the first application, being revealed only later as pregnancy amenorrhea. A premature boy was born with microcephaly, club foot, dislocation of the hip joint, microphthalmia and peromelia of the hands. A phenotypic girl was born two years after the application of the roentgen rays to her mother. Within another year a second boy with peromelia was born. The infant presented stump formation in the upper third of the forearm in the absence of the distal part of the forearm and of the hand. The application of a large dose of roentgen rays to the ovary of the mother during the first five weeks of pregnancy, i. e. during the period in which the fetus is most susceptible to rays, and the presence of microcephaly and microphthalmia frequently described by other authors as characteristic of hereditary damage by rays, strongly suggest that the roentgen therapy applied to the mother was responsible for the malformation of the first child. Animal experiments demonstrated that larger doses of roentgen rays may cause mutation in the first filial generation of mice. The conical hypoplasia of the forearm stump of the second boy with peromelia and the absence of any cicatrization makes it likely that the roentgen rays rather than amniotic adhesions were responsible for the malformation of the arm.

Book Notices

Medical Gynecology. By James C. Janney, M.D., F.A.C.S., Assistant Professor of Gynecology, Boston University School of Medicine, Boston. Cloth. Price, $5. Pp. 389, with 97 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

The presentation is straightforward and consistent and is illustrated with many drawings and reproductions, some of which are taken from standard textbooks. Considerable space is given to pelvic examination and history taking. The symptoms are considered appropriately by headings and presented in an outline fashion under headings of physiologic and pathologic causes. Immediately following this brief is offered the differential points by history, physical examination, pelvic observations and laboratory findings. The treatment of vaginal trichomoniasis is abstracted and the treatment of gonorrhea infection is not quite up to date. In particular there is insufficient emphasis on the use and interpretation of cultures in gonococcic infections. The use of sulfonamides is slightly indefinite, and comments on penicillin are extremely brief and inconclusive. The author gives ample discussions on dyspareunia, frigidity and passion and the sociomedical problems in gynecology. Under the latter heading illegitimacy, abortion, sterilization and contraception are included, with expressions of his views. The discussion on the preparation for marriage and marital maladjustments is straightforward and practical. Throughout the book the history and physical findings and diagnosis stand out. The author adhered to his aims for this publication, as mentioned in the preface, (1) to aid the medical student in correlating the didactic lectures with the experience obtained in the gynecologic clinic and (2) to provide refresher material for the general practitioner. This publication is essentially a diagnostic gynecology, as less attention is given to the therapy. The weaker points can be easily corrected in the next edition. The many good qualities are immediately evident. However, the book will be valuable to both the medical student and the general practitioner, particularly from a diagnostic point of view. The publishers have done remarkably well. Both the author and the publishers can be appropriately complimented.

Studies of Burns and Scalds. (Reports of the Burns Unit, Royal Infirmary, Glasgow, 1942-43.) By *L. Colebrook and others.* Medical Research Council Special Report Series No. 249. Boards. Price, 4s. Pp. 210, with 50 illustrations. London: His Majesty's Stationery Office, 1944.

This small monograph contains a tremendous amount of clinical information about thermal injuries treated at the Glasgow Royal Infirmary during the years 1942 and 1943. About 400 patients admitted to the hospital are represented; 127 cases are summarized and 30 described in detail. Of the 127 cases, 37 were fatal. Six of them were burns involving 20 per cent of the body or under; in 15 of the fatal cases the burns were of 50 per cent or more of the body surface and death occurred within two days. All were treated locally by gentle débridement and cleansing with a detergent and dressed with a cream containing sulfonamide. Anesthesia was not necessary for this procedure; morphine was used as a routine and proved adequate.

Dr. Robert Cruickshank at the Royal Infirmary at Glasgow showed in 1935 that many infections in burns are caused by hemolytic streptococci, which are contaminants and reach the damaged area within a few days after admission to the hospital. These organisms were demonstrated in the air and on the floor of the wards in which the patients were treated. The obvious inference from this important study was the employment of painstaking aseptic technic, with special emphasis on careful avoidance of contamination once the patient enters the hospital. In other words, these studies applied to burns the basic principles of aseptic surgery.

By maintaining a rigid aseptic technic it was possible to demonstrate convincingly a substantial reduction in the incidence of infection. For example, in a series of 282 cases treated with such precautions only 20 passed through an acute suppurative phase due to streptococcic infection, none of which showed any evidence of spreading cellulitis. In another group of 119 patients treated locally with sulfonamide cream, daily temperatures were averaged and charted for a period of twenty-nine days. Half were treated before and the other half after the drive against contamination and cross infection had been instituted. The difference in the two groups was striking. In the group treated aseptically a temperature elevation above 99 F. occurred only on the second day, whereas in the control group the temperature did not drop below 99 F. until the eighth day. Moreover, the level of temperature was consistently lower for the rest of the period in the group handled with careful aseptic precautions. This program to eliminate contamination required painstaking attention to detail, masking of the patient and the personnel, and the education of nurses and attendants. Extending the bandage well beyond the burned area and firmly applying it to the normal skin were also important and prevented the entrance of infection from the outside by the dirty fingers of the patient. The authors also ascribe a definite bactericidal effect to the use of local sulfonamide therapy, which, they admit however is based on a strong impression rather than on any actual objective evidence. Sulfonamides were not used by mouth or by injection.

An interesting and important experiment was carried out on 4 patients who were given intravenous injections of a green dye to determine the extent of the increased capillary permeability. In at least 1 case the center and therefore the more severely burned area remained unstained by the dye. This obviously indicated a type of burn which had destroyed the circulation through the skin and was therefore associated with less extravasation. This observation perhaps was not sufficiently emphasized. It has an important bearing on the general assumption that the amount of fluid lost in a burn and therefore the amount required to correct hemoconcentration varies roughly with the extent of the burn. It seems clear that this would apply only if the entire burned area was associated with extravasation. This would be more likely when the thermal injury did not coagulate the skin, e. g. in scalds. Flame burns, on the other hand, might destroy the circulation through the injured area and thus limit the degree of exudation. Such differences may explain some of the discrepancies between the degree of hemoconcentration and the extent of the burn which the authors noted. These considerations emphasize the need for describing the type of burn present in each case. The title of the monograph "Burns and Scalds" suggested that the cases would be so classified, but this promise was not fulfilled. It might have been profitable to compare the degree of hemoconcentration with the kind of thermal injury (i. e. scald or burn) as well as with its extent. An instructive series of photographs showed the rapidity with which edema of the face subsides spontaneously after a superficial burn. Twenty-four hours after the injury the patient's facial edema, which nine hours before prevented the eyes from opening, had almost completely subsided.

Intravenous injections were carried out rather extensively, the fluid being largely serum or plasma. In some cases concentrated serum was used. The amounts injected were large and by present standards might be called excessive. The indications for the use of intravenous fluids was at first based on the development of hemoconcentration or other evidence of need. Soon this plan was changed to one in which plasma or serum was given early and more or less as a routine in order to prevent hemoconcentration. The latter plan was said to be justified by the results, which, however, on analysis seemed equivocal. Indeed, the authors admit that in at least 1 case there was an excessive amount of intravenous fluid. For example, a 6 year old child with a burn involving but 10 per cent of the body was given intravenously 1,900 cc. (about 75 cc. per kilogram) of plasma during six hours.

Fairly complete studies were made of the degree of hemoconcentration and an attempt was made to correlate this finding with the severity of the burn. While in general the extreme degrees of hemoconcentration were found only in the more severe burns, there were many cases in which the changes in relatively mild burns greatly surpassed those found with more extensive burns. Moreover, hemoconcentration was not infrequently slight or absent in severe burns. Explanation is not offered for this discrepancy, which of course has commonly been observed by many others. Obviously, as pointed out by the authors, factors other than the extent of injury are responsible for hemoconcentration and with it evidence of dehydration

and shock. One of these factors might well be the type of burn actually produced. As indicated, a dry, hard necrosis as produced by flame might involve less loss of plasma and less hemoconcentration than the extensive inflammation resulting from a scald.

Although hemoconcentration was present early in the burn, anemia was observed later, but only in the more serious cases. Red blood cell levels about 50 per cent of normal were reached in practically all of the most extensive burns on the tenth to the fourteenth day. In an attempt to explain this anemia, studies were made of the fragility of the red cells. Significant alterations were observed in the response of the red cells in burn patients as compared with the fragility of the red cells in normal subjects subjected to the same test. Moreover, many patients showed gross hemolysis in their circulating blood and a few contained hemoglobin in the urine. All patients showing hemolysis in the plasma in large amounts were extensively and severely burned, and all except 1 died within twelve hours of injury.

Chemical studies were carried out on many of these burned patients. Following are a few of the general conclusions: There was a rise in blood urea and nonprotein nitrogen in most cases in conformity with the observations of others. The total nitrogen excretion in the urine was fairly large in 1 or 2 cases but did not exceed 17 Gm. per day, which is somewhat less than the findings of others. As the authors state, this may have been due to a small intake of food, particularly by female patients. A fall in the level of plasma protein was observed even though large amounts of serum were given intravenously. Undoubtedly this was due to a loss of protein from the burned surfaces. This was suggested by the fact that the most rapid fall in plasma protein was seen in a case in which exudation was excessive. A striking feature of all burns aside from the very minor ones was the early rise in serum bilirubin. However, the rise was small, and clinical jaundice was never seen early and only once as a terminal event. There was an increased excretion of urobilinogen in 2 cases, which was taken as evidence of disturbance of hepatic function, although it could have been due to increased hemolysis. A transient rise in blood sugar was observed in a few cases during the early hours after the burn.

Postmortem findings are recorded in 30 fatal cases, and these may be summarized in general as being relatively meager, particularly in cases in which death occurred early after the burn. Aside from some edema and congestion in the brain and the occurrence of punctate hemorrhages in various organs and of catarrhal changes in the renal epithelium, little of significance was made out.

This extremely valuable and detailed study will be scrutinized with great interest by all those devoted to the various problems which are still unsolved in the treatment of this distressing injury. It should be read with profit by all who would control the incidence of infection in burns by simple but careful attention to aseptic surgical technic. It will provoke many questions and stimulate further study of the intravenous use of serum and plasma.

Woman's Medical Problems. By Maxine Davis. Cloth. Price, $2. Pp. 220. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1945.

This book was written by a woman reporter of medical news. She is not a physician, nor most likely is she a nurse. Nevertheless the publishers state that "this fine book sets forth in clear and understandable language but with complete authority all that medical science knows about the biologic functions of woman and the condition of disease or misfunctioning that may affect them."

Miss Davis writes "In the course of my many years of writing medical articles in magazines I have received tens of thousands of letters from suffering people from one end of this country to the other. Each month each fresh article brings in hundreds of letters. Ninety-nine per cent of the letters describe symptoms and ask me to recommend treatment or else they ask me to diagnose their illness and tell them what to suggest to the doctor" (page 4). This is a sad commentary on medicine. Authorities in the various fields of medicine should educate the public.

In the chapter on abortion the author dramatizes a story about a woman who wants an illegal abortion performed and must go to a disreputable and shabby physician. She then contrasts this with the recital of how abortions are done by high class abortionists, and this is based on a "description of one the author has seen" (page 56). After women read this ideal way of having a criminal abortion performed the author will indeed be deluged with letters asking for the name of the skilled abortionist whose office and technic she so vividly described.

The author says "a breech presentation means that labor is a little longer for you, but that is all; there is no greater likelihood of complications than in a head presentation" (page 50). Perhaps an increased fetal death rate is not important in the opinion of the author.

In describing cesarean section the author says "Under ideal conditions the risk of dying in a caesarian [sic] birth is only about 2.5 in a thousand" (page 82). Then on page 84 she says "You can see by the very low death rate, which in the case of many good obstetricians sinks to 1.5 per cent, that there is now no more danger in a caesarian section than in any other type of abdominal operation"! In the hands of skilled obstetricians the death rate for cesarean section is less than 1.5 per cent. However, the mortality for cesarean section in the hands of general surgeons and general practitioners is much, much higher than it is for nonobstetric laparotomies.

The author repeatedly quotes a few gynecologists such as Emil Novak and Alan Guttmacher, each of whom has written an excellent book on most of the subjects Miss Davis discusses.

Supervoltage X-Ray Therapy: A Report for the Years 1937-1942 on The Mozelle Sassoon Supervoltage X-Ray Therapy Department, St. Bartholomew's Hospital. By Ralph Phillips, M.S., M.B., F.R.C.S., Sir Halley Stewart Fellow. With the technical assistance of G. S. Innes, B.Sc., A.M.I.E.E., Physicist to the Mozelle Sassoon Department. With a foreword by The Rt. Hon. The Lord Horder, G.C.V.O., M.D., F.R.C.P. Cloth. Price, 16s. Pp. 141, with 95 illustrations. London: Published for the Sir Halley Stewart Trust by H. K. Lewis & Co., Ltd., 1944.

The x-ray department of St. Bartholomew's Hospital, London, under the direction of Dr. N. S. Finzi, presents in this report a summary of the work on supervoltage x-ray therapy for the five years ended in 1942. After this five year trial with a million volt x-ray equipment the author presents this interim report with the hope that the information contained will be helpful to others planning the establishment of radiotherapeutic centers.

A critical assessment of its value is not yet possible, but certain observations are made available, so that this work is a veritable mine of information regarding the technical installation and management of supervoltage x-ray equipment.

The investigation on cancer x-ray therapy really began in 1924 and was limited to carcinoma of the breast, locally inoperable and unsuitable for interstitial radium needling but without distant metastases; carcinoma of the uterus in all stages of the disease; cancer of the upper air and food passages unsuitable for surgery or interstitial radium needling; carcinoma of the rectum, similarly limited, and all cases of carcinoma of the esophagus.

In reviewing the results there does appear to be some advantage in the use of 1,000 volts as compared with 200 kilovolts. It is obvious that the clinical result of radiotherapy of malignant disease does not depend altogether on the wavelength of the radiation employed. If the clinical results depend to a large extent on the physical dose of radiation absorbed in a tumor, then supervoltage x-rays should prove superior to deep x-rays in the treatment of deep-seated tumors of limited extent. It has long been recognized that different types of cancer require different radiation technics for optimum results. Certain differences in favor of supervoltage have been found in the treatment of certain carcinomas, such as maxillary and breast tumors. The unpleasant by-effects of nausea and vomiting and anorexia which sometimes accompany x-ray therapy have been somewhat less noticeable with supervoltage than with 200 kilovolt x-ray treatment. A similar slight advantage relates to the changes produced in the blood picture, intensity of skin reaction and time of healing of tissue reactions.

In short, the author concludes that the results of this investigation permit the definite statement that supervoltage x-ray therapy is superior to deep x-ray therapy (200 kilovolt) in the treatment of certain types of malignant disease.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PROPHYLAXIS AND TREATMENT OF WHOOPING COUGH

To the Editor:—What is the present status of the pertussis vaccines as a prophylactic and in the treatment of pertussis? I refer to the ordinary stock vaccines. The literature concerning the value of pertussis vaccination is confusing: the manufacturers continue to laud them highly. What are the Sauer and Kendrick vaccines? How do they differ from other types? What is the minimum age for the administration of pertussis vaccines?

T. E. Brewer, M.D., Mount Vernon, Ark.

ANSWER.—The present status of pertussis vaccine as a prophylactic or immunizing agent is authoritatively reviewed by Felton and Willard in a Report of the Council on Pharmacy and Chemistry (Current Status of Prophylaxis by Hemophilus Pertussis Vaccine, THE JOURNAL, Sept. 30, 1944, p. 294). It is now the consensus that phase I pertussis vaccine of the proper concentration and dosage will confer prolonged active immunity to children if the vaccine has been kept properly refrigerated and if injection is begun after the sixth month of life. The three doses are given subcutaneously in alternate arms, preferably at monthly intervals. In treatment, vaccine is useless or of questionable value chiefly perhaps because a time interval of at least several weeks must elapse after the final dose before an adequate concentration of specific antibodies has developed. Patients recover because the infecting bacilli stimulate the body to specific antibody production. Intimately exposed but not yet immunized infants and infants already infected should be injected promptly with hyperimmune human serum as prepared by the Philadelphia Serum Exchange (Children's Hospital of Philadelphia). It yields encouraging results when an adequate dose is injected. (Felton, Harriet M.: The Status of Passive Immunization and Treatment in Pertussis, THE JOURNAL, May 5, 1945, p. 26).

A chief difference between Sauer Hemophilus Pertussis Vaccine and that of the Kendrick type is that Sauer vaccine is prepared from bacilli grown on culture medium made with human blood. It is not "washed" and will not sensitize when injected. Northwestern University Medical School authorized Parke, Davis & Co. to market it. Because the Kendrick type of vaccine is prepared from bacilli grown on culture medium made with animal blood, it is necessary to "wash" the harvest to eliminate the alien protein, which might otherwise sensitize when injected. It is prepared at the Michigan State Department of Health and is marketed by several biologic laboratories. Pertussis vaccine made from old stock cultures are inert and should not be used. Sako, Treuting, Witt and Nichamin (Early Immunization Against Pertussis with Alum Precipitated Vaccine, THE JOURNAL, Feb. 17, 1945, p. 379) injected younger infants with three doses of alum precipitated pertussis vaccine. Although pertussis occurred in an appreciable percentage of the children injected so early in life, none who subsequently developed the disease died.

In recent years the use of a mixture of pertussis vaccine and diphtheria toxoid has increased. The infant, however, should be at least 6 or 7 months old before the first dose is given. The alum precipitated mixture yields the best results when the three doses are injected at monthly or bimonthly intervals. Alum abscess can be prevented by the proper injection technic. Such dual immunizations are based on well established laboratory and clinical evidence of effective protection. A five year summary has been published by Sauer, Tucker and Markley (Immunity Responses to Mixtures of Diphtheria Toxoid and Pertussis Vaccine, THE JOURNAL, Aug. 5, 1944, p. 949), who concluded that "infants can be immunized successfully against the two diseases at the same time."

STIFF JOINT AFTER OPERATION ON LIGAMENTS

To the Editor:—In what percentage of patients does a stiff joint result after operation for torn ligaments of the knee joint?

Benjamin Berger, M.D., New York.

ANSWER.—A stiff joint after an operation for torn ligaments of the knee joint should occur only seldom. One reason for a stiff knee following this operation would be an infection which caused a destruction of the joint surfaces, resulting in either a fibrous union or a bony ankylosis between the joint surfaces. There are no figures that would answer the question raised. All one can say is that if a stiff joint follows an operation on the knee it must be due to an infection or a chronic inflammatory joint disease.

COLMETANESE FOR UNDULANT FEVER

To the Editor:—A woman aged 40 is suffering from undulant fever. The agglutination test showed complete agglutination in serum dilutions of 1:20 to 1:40 and partial agglutination at 1:80. The infection apparently was contracted about six years ago. She has had typhoid injections, liver and iron for her secondary anemia and general supportive treatments. The typhoid injections were given about two years ago by a doctor in Texas and I do not know about the results. The patient brought in an ampule of Colmetanese. It is made by Farnsworth Laboratories in Chicago. A doctor in Texas gave her four ampules intravenously, two per week, and these injections together with vitamin B_1 caused a drastic improvement in the patient's condition. She also brought in an article written by O. W. Schreiner, M.D., medical director, Wilson & Co., Chicago, entitled "Brucellosis—A Preliminary Report of Cases Treated with Radioactive Colloidal Manganese." I discussed the matter with a pathologist who had no knowledge of this substance but who advised extreme caution in the use of heavy metals and radioactive substances. What is known concerning this preparation?

M.D., *California.*

ANSWER.—No preparation of the Farnsworth Laboratories stands accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies, and the Council has made no investigation of Colmetanese, which was formerly called Colmanganese. Colmetanese is claimed to be a combination of manganese and radium in colloidal form. According to the promoters "the metal (manganese) is used in an extremely finely dispersed colloidal form, in conjunction with a special ionizing principle so introduced as to give Colmetanese the equivalent of 0.01875 microgram of radium chloride per 10 cc. of solution, and it is the combination of these materials (in the same vehicle) which is responsible for the results described later."

The use of Colmetanese has been proposed for intravenous, intramuscular or rectal administration for a wide variety of disorders including streptococcic and staphylococcic infections, chronic prostatitis, gastric and duodenal ulcers, arthritis, chronic otitis media, mastoiditis, purulent sinusitis, postpartum septicemia, osteomyelitis and pyonephritis, as well as undulant fever. Although strong claims have been advanced for the therapeutic value of Colmetanese, these do not appear to be supported by anything more substantial than a number of uncritical testimonials which cannot be accepted as scientific evidence of the therapeutic worth of the preparation. Colmanganese, now called Colmetanese, has been advertised in connection with the Farnsworth Laboratories' "Alphacatalyst," which is a more recent name for the treatment that was formerly called "Oxycatalyst." This was originally promoted as a cancer cure and was discussed in THE JOURNAL, May 19, 1928. This background information on Colmetanese together with the unusual course of undulant fever, which makes it impossible to give a fair appraisal of any therapeutic agent on a few cases and over a short period of time, does not lead to the development of any confidence whatever in the use of Colmetanese in the treatment of brucellosis.

CUTANEOUS LESIONS AND GONORRHEA

To the Editor:—A man aged 45 has had tumors all over the surface of his body for about ten years. The condition has been diagnosed by skin specialists as von Recklinghausen's disease. His wife, to whom he has been married for fifteen years, acquired gonorrhea from her first husband. She had never been treated for the disease. The patient came to me for treatment of a discharge from the urethra; gram negative intracellular diplococci were found on examination. Treatment has consisted of 2 Gm. of sulfathiazole daily with the result that the discharge has changed from purulent to watery. But more interesting is the fact that the tumors have started to disappear; the skin of his face and neck is almost completely clear, and the other parts of the body are at least 50 per cent better. Is it known that sulfathiazole influences von Recklinghausen's disease?

Ernest Weiss, M.D., Westwood, Calif.

ANSWER.—If sulfathiazole has caused the disappearance of some of these tumors, the condition is not von Recklinghausen's disease. The tumors in von Recklinghausen's disease are new growths of connective tissue, and sulfathiazole would have no effect on them. The lesions of keratosis blennorrhagica, a cutaneous disorder which occurs in connection with gonorrhea, appear as isolated, sometimes confluent, hornlike yellowish brown crusts. However, these lesions occur only during an attack of acute gonorrhea and are accompanied by arthritis and other complications. They do not resemble in any possible manner the lesions seen in von Recklinghausen's disease.

ANURIA

To the Editor:—Would you please let me have the accepted method of treatment of anuria (1) after transfusion of large quantities of blood (5,000 cc.) and (2) after shock, postoperative. Major, M. C., A. U. S.

ANSWER.—The mechanisms of anuria in the instances cited may be the same or they may be of separate origin. 1. After the transfusion of large quantities of blood (5,000 cc.) anuria may result from the condition for which the blood was given, e. g. shock, or from some variety of transfusion reaction. Transfusion reactions may be of three types: that due to an error in performing the conventional crossmatching, that due to the existence of a subgroup such as Rh incompatibility when large amounts of blood or repeated transfusions are used or that due to the presence of isoagglutinins in plasma, serum or group O blood in sufficiently high titer to clump and hemolyze the recipient's cells. M. M. Strumia (*Pennsylvania M. J.* **47**:668 [April] 1944) lists four possible explanations for manifestations of anuria after post-transfusion hemolytic reactions: blockage of renal tubules, anaphylaxis or sensitization to anomalous agglutinogens such as the Rh factor, ischemia of the kidneys from vasoconstriction or nephrotoxic substances released from hemolysis. None of these theories explain all the occurrences, although there is considerable evidence for the theory of toxic nephrosis. Ayer and Kammer (Ayer, G. D., and Kammer, W. F.: *Arch. Int. Med.* **73**:199 [March] 1944) state that intragroup incompatibilities are produced by immune isoagglutinins that develop in the recipient. The factor responsible is usually Rh, and the intragroup transfusion reactions in male patients usually occur after repeated transfusions. The mechanism may be similar to that in crush injury in some instances (Bywaters, E. G. L.: THE JOURNAL, April 15, 1944, p. 1103).

Treatment is largely prophylactic. Careful attention to typing and cross matching and the use of test serums of high potency are essential. Transfusions should be given slowly. When repeated transfusions are done, Rh typing is advisable and, if repeated transfusions of group O blood are used, such blood should have a low titer. Such prophylactic measures are especially important since therapeutic measures are so ineffective. Strumia stated that, "to our knowledge, there is no therapeutic procedure which has proved uniformly successful in the treatment of renal damage following transfusions of incompatible blood. Alkalization, renal decapsulation or sympathectomy, renal pelvic lavage, blood and plasma transfusions and many other procedures have been advocated. In any event it seems logical to maintain an adequate fluid intake and blood volume." Specifically, alkalization can be accomplished by oral or parenteral administration of basic solutions. For prophylaxis, after an initial dose of 4 Gm., 2 Gm. of sodium bicarbonate should be given by mouth in water every three hours (18 Gm. a day). If sodium bicarbonate solution is used by mouth or by vein, 1,500 cc. of isotonic (one-sixth molar) sodium bicarbonate solution should be given daily in divided doses. If sodium lactate solution (one-sixth molar) is used, the dosages are identical. For therapeutic use with already developed anuria, these dosages may not be sufficient and can safely be tripled the first day and thereafter be reduced to the prophylactic dose. Other fluid should be given in addition to the alkaline solution, and in general for every unit of bicarbonate or lactate solution given, an equal quantity of isotonic solution of sodium chloride may be administered. The use of physiologic electrolyte solution (2 parts of isotonic solution of sodium chloride and 1 part of sixth-molar bicarbonate or lactate solution), as advised for burns, can be given by mouth or by vein for the purposes of alkalization. Such a solution in double or triple the prophylactic dose mentioned supplies the alkali and saline in a combined form.

2. After postoperative shock, anuria may develop as a result of the shock itself, from transfusion reactions or from the anesthesia. In postoperative shock a crush syndrome-like mechanism is seldom operative except in extremity cases when there has been a tourniquet on the extremity during operation or in instances of release of large segments of strangulated bowel. Most often the anuria results from a profound and continued fall in blood pressure with associated decreased renal flow. Such damage may be permanent or may be temporary. Injury to the kidneys by anesthetic agents either with or without prolonged blood pressure fall has been studied by Coller (Coller, F. G., and others: *Ann. Surg.* **118**:717 [Oct.] 1943).

Treatment consists in preventing and managing shock in the usually accepted ways by the administration of plasma, whole blood and adequate fluids and in using controlled anesthesia. Large doses of spinal anesthesia are especially dangerous in hypertensive patients. When anuria has already developed despite antishock measures, the methods of treatment listed in the previous section, alkalization and administration of fluids, can be tried but are not always successful.

ASTHMA AND TUBERCULOSIS

To the Editor:—A physician has had moderately severe bronchial asthma for eight years, presumably due to multiple allergens. Exhaustive diagnostic tests have failed to reveal any specific etiologic factor or factors. Inhalations of a solution of 1:100 epinephrine hydrochloride by nebulizer generally give a fair degree of relief. Use of epinephrine is necessary two to four times a week. This physician has contended that with this condition present it would be unwise for him to perform duties in a tuberculosis hospital. M.D., Ohio.

ANSWER.—From the description given it is fairly safe to assume that the case described is one of moderate rather than of severe asthma, since inhalation of a solution of 1:100 epinephrine gives a fair degree of relief and is not required more often than two to four times a week.

The literature is full of contradictions as to whether such an individual is more likely to develop tuberculosis than the average adult. However many of the older writers (Rokitansky, Bruegelman, Schroeder) were of the opinion that asthma and tuberculosis are seldom found together. More recent authors are inclined to the opinion that tuberculosis does not occur more frequently in patients with asthma than in persons suffering from other diseases. With the exercise of ordinary precautions the physician who has the degree of asthma indicated in this question should be able to work in a tuberculosis hospital with no more danger than if he did not have asthma.

EFFECT OF HEAT ON MUCOSA OF RECTUM AND COLON

To the Editor:—What work has been done on the effect of heat, as from a hot enema on the rectal and colon mucosa? Has there been any comparison made between a lesion so produced and that produced by chemical irritation? Is there any reference in the literature to the medicolegal implications? M.D., Pennsylvania.

ANSWER.—The medical literature is conspicuously devoid of contributions concerning the effect of heat on the mucosa of the rectum and colon. In the discussion of a paper by Ault dealing with perforation of the rectum with enema tips (Ault, G. W.: Perforation of Rectum with Enema Tips, *Tr. Am. Proct. Soc.* **40**:203, 1939 Murray briefly cites 1 case with fatal termination four days after administration of an enema "at too high a temperature." Death was attributed to shock and sepsis following intestinal burns. There has been no known reported comparison made between a lesion produced by the effect of heat and that produced by chemical irritation. There is no reference in the available textbooks on medical jurisprudence with respect to the medicolegal implications.

PENICILLIN AND PROCAINE HYDROCHLORIDE

To the Editor:—I have recently treated multiple furunculosis (boils) by infiltration with a solution of penicillin and procaine hydrochloride. The results were successful far beyond expectation. This solution was prepared by taking 1 cc. of penicillin solution, 20,000 units per cubic centimeter, in a sterile syringe and then drawing 1 cc. of 2 per cent procaine hydrochloride solution into the same syringe. The mixture was agitated a little and then infiltrated into the furuncle slowly. The amount of injection depended on the size of the furuncle and ranged from 0.1 to 0.5 cc. Thus the syringe contained enough for several furuncles. The furuncles healed rapidly and there was no after-pain as commonly found with straight penicillin. I have been wondering what effect procaine hydrochloride has on the stability or activity of penicillin when mixed together and used immediately as described. Alex J. Otten, M.D., Grand Forks, N. D.

ANSWER.—There is no evidence that mixing procaine hydrochloride has any deleterious effect on penicillin when it is mixed with it and used immediately as described. This method has been used frequently to avoid painful reactions when penicillin of low potency is injected intramuscularly.

POSSIBLE FROEHLICH'S SYNDROME

To the Editor:—The answer to the query on "Possible Froehlich's Syndrome" in The Journal, May 26, 1945, page 318, contains certain inaccuracies. In the first place, contrary to the statement made, gonadotropic hormones are capable of increasing the gonads and frequently also the genitalia and other sexual characteristics. Secondly, x-ray films of the skull detect mainly disturbances in the growth hormone fraction, which does not seem disturbed in this case. Abnormalities in the size of the sella are inconclusive in most cases, and absent or too small size of sinuses are not indicative of gonadotropic dysfunction per se. Thirdly, the basal metabolic rate will probably be normal and any possible small deviation will not be helpful in the diagnosis or plan of treatment. Of greater value would be a determination of the blood cholesterol and uric acid.

LIEUTENANT COLONEL A. B. SABIN
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

LIEUTENANT COLONEL C. B. PHILIP
SANITARY CORPS, ARMY OF THE UNITED STATES

In this paper we describe our experiences with the transmission of serum (or plasma) jaundice and infectious hepatitis. Actually these two conditions may be closely related in that the former may represent the artificial production of the latter; but, while this may be true in some instances, it cannot yet be said that all serum jaundice belongs in this category. The etiologic agents in both of these conditions appear to be quite similar, and this holds for the clinical picture, which in both resembles "catarrhal jaundice." On the other hand there are differences which are poorly understood and can be best illustrated perhaps in terms of transmission experiments.

HOMOLOGOUS SERUM JAUNDICE

Homologous serum jaundice is not easy to define. It is produced by the parenteral inoculation of whole blood, serum or plasma, ordinarily obtained from an individual who is supposedly nonjaundiced, or at least from a donor not known (at the time) to be ill with infectious hepatitis. Such a definition is highly artificial, as is also the disease itself. But this does not detract from its significance, for serum jaundice is an important and common entity, with numerous examples resulting from the prophylactic injection of serum for measles,[1] mumps,[2] other virus diseases [3] and also from vaccines containing serum,[4] as well as from the experimental injection of some of these serums.[5] It appears that the "icterogenic capacity" of various lots of serums differs as far as the rates at which jaundice is produced and the lengths of the incubation periods are concerned.

The agent of serum jaundice has not been actually "isolated" in the sense that it has been seen, cultured or transmitted to laboratory animals, in spite of repeated attempts by Findlay and Martin,[6] Oliphant and his associates [7] and Sawyer and his associates.[8] It is known to be filtrable and to be sufficiently heat resistant to withstand 56 C. for one hour.[7] It produces jaundice in human beings somewhat irregularly when given parenterally, with a clinical picture not unlike that of infectious hepatitis (table 1). The incubation period is long (seventy to one hundred days or more) although mild hepatitis may occur early in this long incubation period—many days before true jaundice is actually recognizable.[9]

Serum jaundice has been transmitted in human beings by feeding serum in 1 instance,[10] and it is possible that this has been accomplished with nasopharyngeal washings.[6]

Our own transmission experiments with serum jaundice were first carried out in the Middle East (first series, chart 1) and later supplemented by work in this country (see second series). Twenty-six individuals

From the Middle East Laboratory of the Commission on Neurotropic Virus Diseases and the Section of Preventive Medicine, Yale University School of Medicine.

These investigations were aided in part by the Commission on Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army.

Assistance was received from Col. D. W. Billick, M. C., Lieut. Col. Thomas G. Ward, M. C., Col. Hall G. Van Vlack, M. C., Lieut. Col. R. B. Nye, M. C., Col. O. B. Bolibaugh, M. C., and Dr. S. F. Price, U. S. Public Health Service.

Assistance and cooperation were given by the Selective Service, Camp Operations Division; Civilian Public Service Unit No. 68; Civilian Public Service Unit No. 81; the Norwich State Hospital, Norwich, Conn.; the Connecticut State Hospital, Middletown, Conn., and the Federal Correctional Institution, Danbury, Conn.

were tested. The icterogenic agent used was originally derived from a serum pool collected from British and American troops in the course of studies on sandfly fever in Egypt.[11]

Material from this inoculum (pool 1) produced sandfly fever in 9 out of 10 inoculated volunteers after the usual incubation period of from three to five days. Beginning at about seventy days after the first inoculation and sixty days after the attack of sandfly fever was over, a member of this group of 10 volunteers developed jaundice and suspicion was immediately aroused that besides the virus of sandfly fever there had also been an icterogenic agent in pool 1. The original acute sandfly fever patients who had acted as donors for the blood samples in pool 1 had all been living (during June 1943) within an area endemic for infectious hepatitis, although at the time the samples were obtained the prevalence of this disease was low. The donors had been questioned specifically at the time the blood was drawn and had stated that they had not had jaundice recently. Attempts were therefore made in October 1943 to trace the fate of these donors. Information was obtained from 10 of them. None of these reported having had jaundice during the four month period after they had been bled (June to October 1943). The eleventh man had left the country and could not be traced.

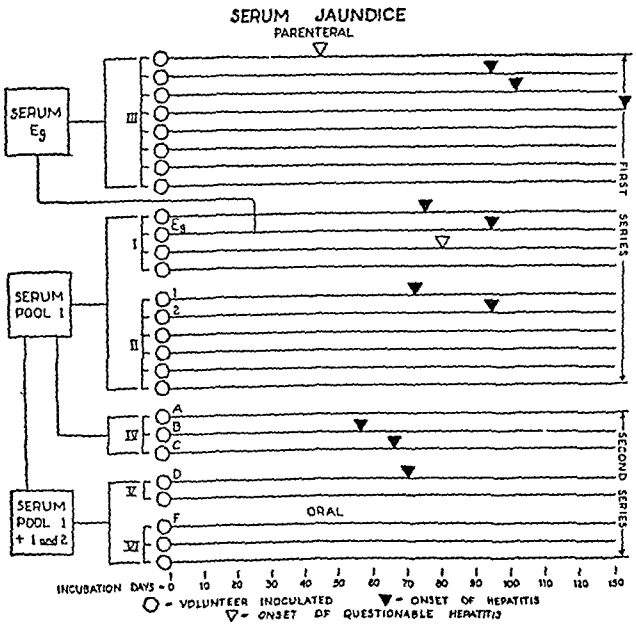

Chart 1.—Results of administering icterogenic serum (homologous serum jaundice) to six groups of human volunteers, each subject being represented by a horizontal line. The six groups are indicated by the Roman numerals at the left of the column of circles. The first series and the second series (indicated on extreme right) represent experiments done in the Middle East and in the United States respectively.

TABLE 1.—*Experimental Serum Jaundice Produced Parenterally in Human Volunteers*

Author	Serum Inoculum	Number Tested	Number Positive *	Incubation to Onset of Jaundice †
Oliphant and others [7]	In yellow fever vaccine and serum of vaccines	189	30	28 - 133
MacCallum and Bauer [10]	Various types homologous serums	5 11	2 4	63 - 70 59 - 129
Neefe and others [9]	Mumps convalescent	6	5	73 - 110
	Passage of foregoing	2	0	
	In yellow fever vaccine	2	1	99

* Only those men who developed clinical jaundice are listed as positive. Hepatitis without jaundice also occurred.
† Days between inoculation and onset of jaundice

In spite of inability to ascertain its source, suspicion that there was an icterogenic agent in our pool 1 was well grounded, for in due course 3 more of the 10 volunteers developed hepatitis, giving us an incidence of 40 per cent. This occurred during the local hepatitis season (October to February), but actually the prevalence of infectious hepatitis at the desert camp where the volunteers were quartered was very low (under 0.5 per cent) at this time, in contrast to the higher prevalence of the disease in adjacent areas.

Details of these inoculations are recorded in table 2. Here the volunteers, listed as groups I and II, are seen to total 10 men in all. Four of them developed jaundice after incubation periods ranging from seventy-two to ninety-four days. Two other members of the whole group of 10 were ill with a nonicteric illness during the same general period (September to December 1943); viz., 1 volunteer (Pvt. Dk.), who had a history of psychasthenic difficulties in the past, became nervous and depressed and was hospitalized for a period of two months. Jaundice was not clinically evident in this patient. Another (Pvt. By.) was hospitalized during December with the diagnosis of atypical pneumonia.

The next experimental cases occurred in group III (table 3), consisting of 8 subjects who had submitted to skin tests on Aug. 21, 1943. The tests were performed with serum obtained from Pvt. Eg. on Aug. 18, a member of group I. The blood was drawn from Pvt. Eg.

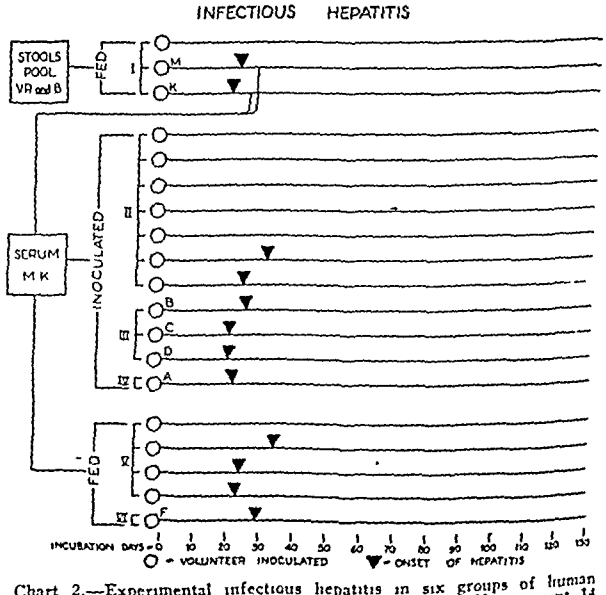

Chart 2.—Experimental infectious hepatitis in six groups of human volunteers. Legends as in chart 1. Groups I, II and V represent 14 normal subjects. Groups III, IV and VI represent 5 subjects, B, C, D, A and F, all used six months previously in the serum jaundice experiment in chart 1, second series. Three of these subjects, B, C and D, were convalescent from serum jaundice. The stools pool (see upper left) consisted of (VR) a pool of dehydrated Seitz filtrates of stool and urine extracts from British soldiers in various stages of infectious hepatitis, prepared by Major C. E. van Rooyen, R. A. M. C., and (B) a stool obtained eight days after the appearance of jaundice in an American soldier with infectious hepatitis.

thirty-four days after his first inoculation with icterogenic serum (on July 15) and sixty days prior to the date on which he developed jaundice. In other words, the sample was obtained during the early part of a long

11. Sabin, A. B.; Philip, C. B., and Paul, J. R.: Phlebotomus (Pappataci or Sandfly) Fever, a Disease of Military Importance, J. A. M. A. 125:603 (July 1), 693 (July 8) 1944.

incubation period, preceding his attack of serum jaundice. Eg.'s serum was heated at 56 C. for half an hour before it was used for skin testing the 8 persons in group III. Of the 8 persons who received 0.1 cc. of Eg.'s heated serum intracutaneously, 3 developed jaundice after incubation periods ranging from ninety-four to one hundred and thirty-two days (table 3). Besides these 3, 2 other members of group III contracted nonicteric illnesses during the one hundred and thirty day period following the skin tests; viz., 2d Lieut. Cs. (a nurse) was hospitalized between October 4 and November 14 suffering from indefinite symptoms of malaise and diarrhea. The exact nature of her condition was not determined. She was discharged from the hospital with a diagnosis of pyelonephritis (mild, nonsuppurative) and anemia (type undetermined). Another person, T/3 Td., was hospitalized for a short time beginning November 20 with the diagnosis of respiratory infection. There was no evidence of jaundice in these 2 patients.

These experiments were repeated several months later in the United States (see second series in chart 1). Pool 1 alone (and mixed with first passage serums) was used. It produced serum jaundice in 3 of 5 volunteers inoculated parenterally. Three attempts to produce jaundice by the oral administration of this icterogenic serum were negative.

It thus appears that jaundice was produced parenterally 10 times in 23 individuals with different (first and second) passages of this icterogenic material and that the incubation period was invariably long (fifty to one hundred and thirty-five days).

INFECTIOUS HEPATITIS

Infectious hepatitis has an older and less artificial history. It is common and widespread and in the present war, as in former wars, has been prevalent among the troops. As far as published records are available, this seems to have been especially true of British forces in the Middle East,[12] but the disease has not been limited to the British or to that particular geographic area, for it has occurred in the French army in Tunisia,[13] in the Italian army in Sicily in 1941 [14] and in the German army.[15] American troops in North Africa [16] and Italy have not been spared.

There is as yet no good reason to believe that this Middle Eastern type of infectious hepatitis differs from that which has been noted in the United States [17] or differs from the disease frequently described as infective hepatitis in England [18] or as hepatitis epidemica in Scandinavia,[19] Germany [20] and many other parts of the world. There is still no ready means of differentiating it from catarrhal jaundice,[21] except that the latter term has been applied more to sporadic than to epidemic cases. These and other questions deserve extensive further study, but on two points at least

there is universal agreement; namely, infectious hepatitis can be differentiated from spirochetal jaundice (Weil's disease) and from yellow fever.

The manner in which infectious hepatitis spreads from person to person is not completely known, but the intestinal-oral circuit has long been suspected.[22] Recently this has been proved experimentally to be one means of transfer.[23] Not only does the disease flourish under poor sanitary conditions but it frequently (although by no means always) follows outbreaks of intestinal disease. Kirk's study[24] of infectious hepatitis among New Zealand soldiers at Alamein in Egypt in 1942 led him to believe that the disease was spread by flies carrying the infection from human excreta.

Exact knowledge as to immunity in this disease is not yet available. It has been noted that troops newly introduced into an endemic or epidemic area are more susceptible to infectious hepatitis than is the local population. This observation has been made in Egypt[25] (where the disease has been regarded by civilian doctors as essentially one of childhood), in Palestine,[26] in Malta[27] and elsewhere. This suggests but does not establish the fact that immunity is readily acquired. On the other hand, second attacks are said to occur. It is also pertinent to mention that (with the exception of one experimental report by Oliphant[28]) there is little evidence that immunity to infectious hepatitis is induced by an attack of serum jaundice or of "catarrhal jaundice."

Etiologic Agent.—Like that of serum jaundice, the agent of infectious hepatitis has not been transmitted to laboratory animals in spite of attempts by van Rooyen and Gordon,[12] Cameron[29] and others. In our own laboratories both in the Middle East and in this country we have tried in vain to transmit infectious hepatitis to white mice, guinea pigs, hamsters, gerbils, Cercopithecus, Erythrocebus and Macacus monkeys and Abyssinian baboons. It is possible that the type of jaundice transmitted to pigs in Denmark by Andersen[30] was infectious jaundice of this type. More recently Siede, working with Meding, and Luz[31] in Germany, claims to have propagated this agent in the developing chick embryo, and Dresel and his associates[32] claim to have infected birds with it. These reports have not been confirmed. Nevertheless it has been passed serially in man (two passages), thus conclusively indicating the infectious nature of the disease[33] and by using man as the experimental animal some of the properties of the agent of infectious hepatitis have been determined. Thus, like the agent of serum jaundice, it also has been found to resist heating at 56 C. for one-half hour and to pass bacteria tight filters.[33] As in serum jaundice, the agent or virus is present in the blood stream during active stages of the disease[34] and for an indeterminate period before the onset of jaundice. It is similarly present in feces[35] and perhaps in the urine.[36] Furthermore, experimental infectious hepatitis can be readily produced in man by the oral route[35] (table 4).

* Only those cases in which clinical jaundice developed have been listed as positive
† sc = subcutaneous; ic. = intracutaneous, im = intramuscular; iv. = intravenous; in. = intranasal and in most cases intrapharyngeal.

Among early claims of success at transmission are those of Voegt[37] in Germany. Details are incomplete, but Voegt described having infected 1 out of 4 volunteers by feeding them duodenal fluid. He also claimed that he produced hepatitis experimentally by the inoculation of human serum and by the ingestion of urine and of hemolyzed red blood cells.

In Cameron's investigations,[29] carried out in Palestine, serum and whole blood from cases of hepatitis were injected intramuscularly. Seven volunteers were inoculated, of which 6 could be followed. All of these developed jaundice, although details as to the time of onset are not available.

Most significant experiments have been recently reported in a short note by MacCallum and Bradley,[38] who found the virus in the feces, and that the disease can be induced (after a "thirty day" incubation period) by feeding such material to arthritic patients who volunteered for these experiments. The infective fecal material was collected from several patients in the early stages of infectious hepatitis. A few positive results were also obtained both from nasopharyngeal washings (which gave rise to subicteric hepatitis in volunteers) also after a relatively short incubation period—twenty-seven to thirty-one days.

These results have been independently duplicated and somewhat enhanced by Havens and his associates [39] in our own laboratory of the Neurotropic Virus Disease Commission of the U. S. Army, where healthy human subjects have been used for the tests. The infective material was also collected from American and British troops during acute stages of infectious hepatitis acquired in the Middle East and Mediterranean area. It was kept frozen until administered by various routes to several groups of human volunteers in the United States (chart 2). The most important findings can be summarized as follows:

When fecal material from patients with the naturally occurring disease was fed to human volunteers, 2 out of 3 contracted the disease in twenty and twenty-two days respectively.[39] Serum obtained from these 2 patients in the preicteric phase was filtered (Chamberland number 2) and immediately afterward heated (56 C. for thirty minutes). This heated serum filtrate (MK) produced infectious hepatitis when fed to 4 of 5 human volunteers with an incubation period ranging from twenty-three to thirty-four days. The same material was simultaneously inoculated parenterally in the same amount and produced infectious hepatitis in 6 of 11 volunteers with an incubation period ranging from twenty to thirty-one days.[40] Some of the latter group of volunteers had recovered some months before from serum jaundice, but this did not protect them against an attack of infectious hepatitis.[40]

It thus appears in experiments with one strain of the virus that jaundice was produced 6 times in 11 subjects when the virus was inoculated and 6 times in 8 subjects when the virus was fed and that the incubation period was invariably less than thirty-four days in these experiments.

SUMMARY

Transmission experiments in man have enhanced our knowledge of serum jaundice and infectious hepatitis.

In serum jaundice the interval between inoculation and the development of symptoms is usually relatively long, averaging from sixty to one hundred and twenty days.

The agent (or "virus") of serum jaundice is in the blood during active stages of the disease and also during the interval between inoculation and the development of serum jaundice. In 1 instance it was present in blood obtained sixty days prior to the onset of jaundice.

Experimental work indicates that the agent or agents of serum jaundice and of infectious hepatitis are quite similar, as is also the clinical picture of the disease produced, resembling, as it does, the picture of catarrhal jaundice.

The agent or agents of serum jaundice and of experimental hepatitis are both filtrable and both relatively resistant to heat.

A prominent difference between serum jaundice and infectious hepatitis, yet to be explained, lies in the length of the incubation period, which may be quite variable, but in our experimental cases of infectious hepatitis it tended to be from eighteen to thirty days, in contrast to the sixty to one hundred and twenty day incubation period of experimental cases of serum jaundice.

Three patients who had recovered from serum jaundice six months before were not found to be immune to experimentally induced attacks of infectious hepatitis. However, little is known regarding immunity in infectious hepatitis, and the ease with which these 3 patients were "reinfected" is not regarded as an indication that the two diseases are fundamentally different.

The virus of infectious hepatitis is in the blood and in the feces during active stages of the disease.

Infectious hepatitis can be readily produced in man by the oral route. This can be accomplished by feeding infective feces or by spraying such material into the nasopharyngeal passages. Similarly the disease can be produced by feeding infective serum as well as by its parenteral administration.

EXTRATHYROID EFFECTS OF THIOURACIL THERAPY

ELLA H. FISHBERG, M.D.
AND
JEFFERSON VORZIMER, M.D.
NEW YORK

Thiouracil, a derivative of thiourea, exerts a powerful depressant action on the production of thyroid hormone and hence has been applied clinically to secure reduction of the basal metabolic rate in thyrotoxic patients. During the past twenty-one months we have used thiouracil in the treatment of a series of 96 patients with hyperthyroidism, which in many of the patients was complicated by other conditions and, in addition, there were several who were reluctant to undergo a second operation for recurrent hyperthyroidism. We have been much impressed by the favorable effect of the drug on these extrathyroid complications caused by the heightened basal metabolism or by a disturbance of glandular equilibrium, or both. As the basal metabolic rate fell, we observed a high degree of amelioration in the cardiac sequelae, great lessening of the associated diabetes, decrease in exophthalmos and improvement of the psychic state. On the other hand, in contrast to previous reports, we have encountered a much higher incidence of granulopenia, about 20 per cent, including 1 case of typical agranulocytosis.

In general, the dosage was 1 Gm. daily for three days, followed by 0.6 Gm. until the basal metabolic rate dropped to within normal limits, approximately + 10 or less. In the 15 cases of sustained remission for periods between two and fifteen months, all medication was dropped. In every case in which more than 0.2 Gm. was administered daily, it was a fixed rule that a white blood count had to be made every three days, and a differential count, if there was over 20 per cent drop in

From the Biochemical Laboratory and the Medical Division of the Beth Israel Hospital. With the technical assistance of Virginia Rechnitzer, B.A.

the total number of leukocytes. When the maintenance dose was reduced to 0.2 Gm. or less and the leukocyte count remained within normal limits, 0.2 Gm. daily was given for one week, no medication for the second week and 0.2 Gm. daily for the third week. A blood count was then made. This method reduces the necessary blood counts from one every three days to one every three weeks and sufficient thiouracil is administered to maintain the basal metabolic rate within normal limits. There were no restrictions put on the patients, who were freely ambulatory.

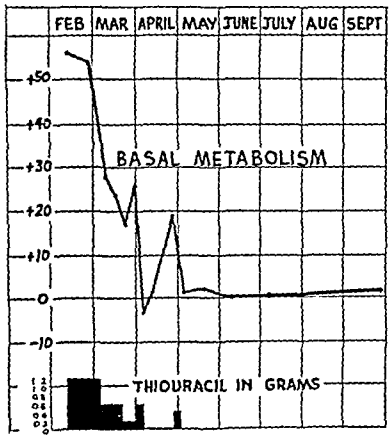

Chart 1.—Drop in basal metabolic rate in an uncomplicated case of hyperthyroidism The patient continued work as a welder in a shipyard during the entire period of therapy apparently in continued remission.

The first response was subjective. After seven to ten days the patients stated that they felt calmer. Charts 1, 2 and 3 sum up the metabolic changes. With lowering of the basal metabolic rate there were objective signs of loss of agitation, decreased perspiration, decrease to loss of tremor and disappearance of diarrhea. It was striking that there was a lag in the slowing of the pulse and in the gain in weight, particularly the latter. In some cases there was even a slight loss of weight during the first weeks of active treatment, but following this there was a gradual gain, amounting in 1 case to 55 pounds (25 Kg.). In many cases loss of tachycardia did not occur until a considerable period after the drop in basal metabolic rate. This lag in response would perhaps be expected from the pharmacologic action of the drug. Shortly after thiouracil is taken the rate of synthesis of the thyroid hormone falls and the thyrotropic hormone of the pituitary, released in excess, stimulates the thyroid gland and liberates the hormone stored therein. When this accumulated thyroid hormone is used up, since none is now being produced, the basal metabolic rate falls. Contrary to the findings in animal experiments, we were unable to note any increase in size of the thyroid gland or increased exophthalmos in human beings as a result of thiouracil therapy. On the contrary, we found a decrease in one or both, in the majority of cases.

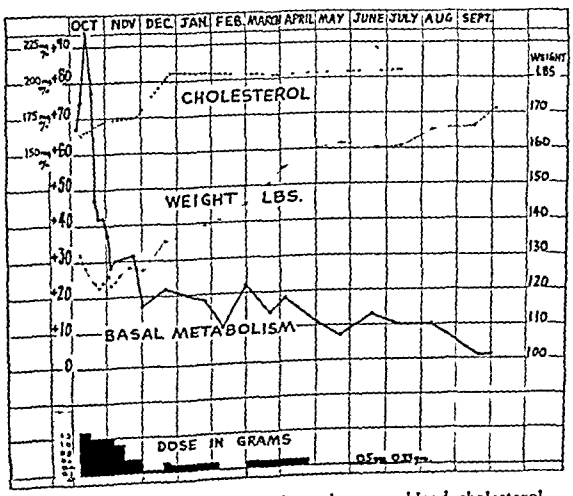

Chart 2.—Lag in gain in weight and rise in blood cholesterol.

Our results would point to thiouracil therapy as an ideal method for securing reduction in basal metabolic rate with a minimum of effort. It entails no interruption of the patient's normal occupation nor prolonged periods of rest and often avoids the necessity of operation, were it not for the ever possible danger of granulopenia and true agranulocytosis if the drug is not stopped forthwith. There seems to be no cumulative action of the drug itself, because 1 patient who developed granulocytopenia (chart 4) showed a maximum thiouracil concentration of 3 mg. per hundred cubic centimeters [1] in the blood with a normal excretion, while another with no drop in the white count showed a concentration of 6.75 mg. per hundred cubic centimeters. Rabbits, carried along for months on the comparatively enormous dosage of 0.1 Gm. daily, with a concentration of 9 mg. per hundred cubic centimeters in the blood, showed no granulopenia nor bone marrow changes. It can be seen from chart 4 that three separate attempts were made to reinstate thiouracil therapy but each time neutrophilic granulopenia followed. One patient developed granulopenia on the eighty-fifth day of therapy, while the white count of another patient dropped from 8,100 to 4,400 thirty-six hours after taking the drug. In the following cases thiouracil therapy had to be interrupted and finally terminated because of intolerance to the drug, manifested mainly by a toxic effect on the bone marrow:

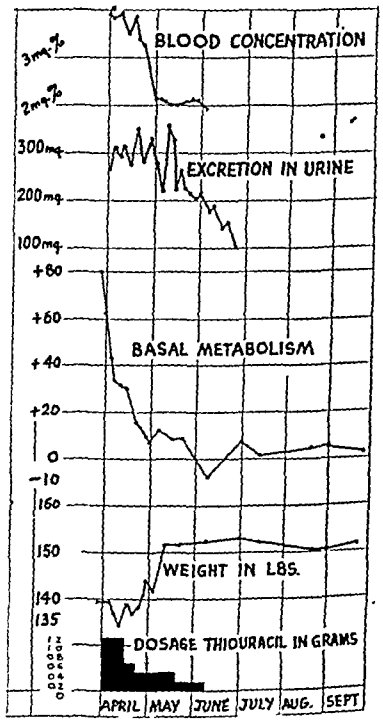

Chart 3.—Typical concentration of thiouracil in blood and excretion in urine during period of intensive therapy.

Case 1.—E. F., a woman aged 38, was admitted with a three months history of nervousness, loss of 19 pounds (8.6 Kg.), sweating and palpitation. Examination revealed agitation, tremor, sweating and enlargement of the thyroid. The basal metabolic rate was + 41. After 1.2 Gm. of thiouracil had been given for ten days there was a drop in white blood cells from 9,700 to 5,000 with a pronounced decrease in granulocytes. No constitutional reaction was noted. At this time the basal metabolic

1. A very simple method, using the reagent for the detection of acetone that is found in every laboratory, was developed for the clinical determination of thiouracil in blood, urine or body tissues. It was based on the finding by Grote that sodium nitroprusside, when treated by various reagents, gives a color with compounds containing a sulfur radical in organic combination. We found that thiouracil will give a green color when treated with sodium nitroprusside which has been exposed to the action of ultraviolet light for two and three-fourths hours Method: To 1 cc. of blood serum or urine there is added 1 cc. of a 5 per cent solution of irradiated sodium nitroprusside and 1 cc. of a buffer phosphate solution of pH 5.5. After ten minutes a green color develops which can be measured in a colorimeter or photoelectric colorimeter (red filter) against a standard solution of thiouracil similarly treated Grote, I W L A New Color Reaction for Soluble Organic Sulfur Compounds, J Biol Chem. 93: 25, 1931.

rate dropped to + 13. Because of the toxic effect on the bone marrow, the patient was prepared for operation. Thyroidectomy was performed. There was no excessive bleeding at operation and the patient made an uneventful recovery.

CASE 2.—L. S., a woman aged 30, married, admitted to the hospital with a history of palpitation, oligomenorrhea, nervousness, excessive perspiration and diarrhea of several months' duration and a loss of 10 pounds (4.5 Kg.) in one month, had noted prominence of the eyes and enlargement of the neck.

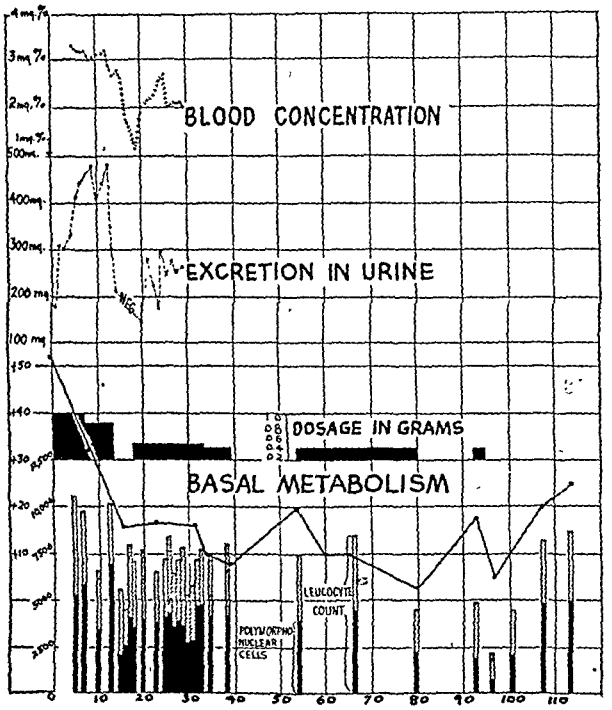

Chart 4.—Three attempts to reinstate thiouracil therapy in a patient sensitive to thiouracil.

Examination revealed agitation, tremor, perspiration and tachycardia, with slight exophthalmos. The basal metabolic rate was + 58. Cholesterol was 178 mg. per hundred cubic centimeters. Thiouracil therapy was inaugurated on February 1 with a dosage of 1.2 Gm. daily. After the first week the patient noted that she felt calmer and that the sweating was much less. The basal metabolic rate fell steadily so that it was + 54 on February 16, + 44 on February 21 and + 29 on February 25. On the morning of the 26th the patient complained of severe headache, pains in the legs and nausea, and she felt chilly. There was a rise in temperature to 104.4 F. At this time generalized enlargement of the lymph nodes was noticed. The nodes were firm, discrete and almost 1 cm. in diameter. Some were tender and others only slightly so. The spleen was not palpable. The white blood cell count was 9,700, with 80 per cent polymorphonuclear cells. No rash was seen. Thiouracil was stopped and the temperature returned to normal. The adenopathy persisted and the white blood count dropped to 5,800. By February 28 the adenopathy had disappeared and the basal metabolic rate was found to be + 7. On the 29th thiouracil was ordered. Following the second dose there was a recurrence of headache, muscular pains and chilliness, with a rise in temperature to 103.6 F. Examination again revealed lymph node enlargement but no rash. Because of the definite intolerance to the drug, this therapy was not attempted again. Only after two months had this patient shown a high degree of sensitivity to the drug. Since the hyperthyroidism had been so well controlled, thyroidectomy was performed at once. As in case 1, no excessive bleeding was noted. The postoperative course was uneventful and the patient was discharged on the thirteenth postoperative day with a basal metabolic rate of + 1.

CASE 3.—E. E., a woman aged 35, married, admitted in July 1944, complained of weakness, loss of 20 pounds (9 Kg.), nervousness, excessive perspiration, palpitation and tremor of four months' duration. Examination revealed typical hyperthyroidism with no exophthalmos or palpable enlargement of the gland. The basal metabolic rate was + 70. Cholesterol was 152 mg. per hundred cubic centimeters. Thiouracil .1 Gm. daily was started on July 17. On the 19th the dose was reduced to 0.6 Gm. The white blood cell count varied between 6,700 and 7,600, with 60 to 70 per cent polymorphonuclear cells until July 28, when there was a sudden drop to 4,800 with 20 per cent polymorphonuclear cells and the patient complained of diffuse myalgia and arthralgia. This was associated with a rise in temperature to 103 F., generalized lymph node enlargement and a palpable spleen. Thiouracil was stopped and within twenty-four hours all signs of a reaction had disappeared, with the temperature returning to normal within twelve hours. During the next two days, in spite of a normal white count, the granulocytes were only 42 per cent. The patient was then given Lugol's solution and referred to the surgical service, where thyroidectomy was performed. There was no increased bleeding and the postoperative course was uneventful.[2]

CASE 4.—Y. L., a woman aged 37, a nurse, was admitted on March 14, 1944 with complaints of nervousness and perspiration, frequent diarrhea, increasing prominence of the eyes and loss of 11 pounds (5 Kg.) in two months. Examination revealed tachycardia, an enlarged thyroid, especially the right lobe, exophthalmos more pronounced on the right side, perspiration, agitation and tremor. The progress of the case is shown on chart 4, and it can be seen that three separate attempts were made to resume thiouracil therapy after a drop in the white count, with a drop at the last attempt to 2,200 white cells and 38 per cent polymorphonuclears. At no time was there any other warning of bone marrow depression, and the patient never stopped work as a nurse on night duty in this hospital.

CASE 5.—B. A., a woman aged 50, was admitted to the hospital with a history of nervousness, palpitation, profuse sweating, and loss of 21 pounds (9.5 Kg.) in two years. Enlargement of the thyroid was noted a few months before admission. The patient had been given Lugol's solution but had taken none for nine months prior to admission. Examination revealed agitation, excess sweating, tachycardia and enlargement of the thyroid gland. The basal metabolic rate was + 53. Thiouracil 1.2 Gm. was given for three days and then reduced to 0.8 Gm. After

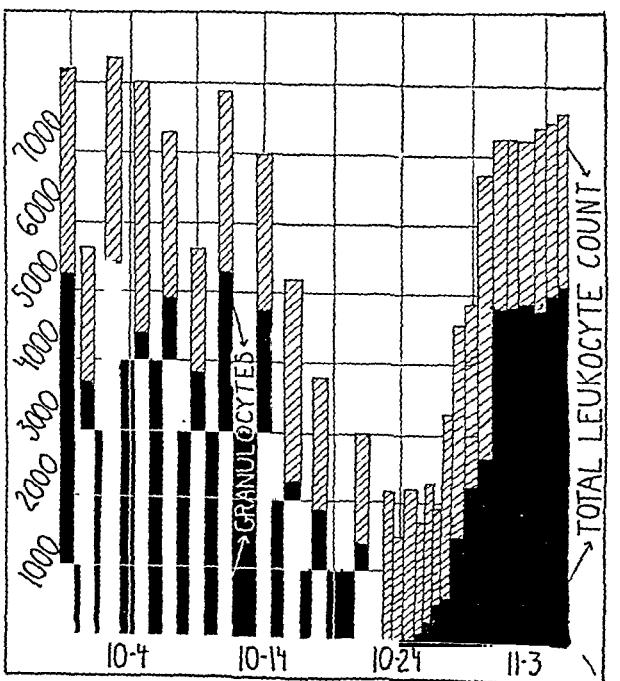

Chart 5.—Development of agranulocytosis from failure to stop administration of thiouracil.

2. The pathologic report on the thyroids in these 3 cases stated that they were well within the range of variation for a larger group of hyperthyroidism specimens.

four weeks of hospitalization the basal metabolic rate dropped to + 23. There was a gain of 11 pounds (5 Kg.) in weight. She was discharged from the hospital and treated as an ambulatory patient. On October 16 her basal metabolic rate was + 19, but the white blood count had fallen. She complained of a sore throat, had a temperature of 104 F. and after a sternal puncture was made she was readmitted to the hospital. Sternal puncture revealed a normocellular marrow with slightly decreased myelocytes and myeloblasts, and a pronounced decrease in polymorphonuclear leukocytes, many very young red cells and platelets in abundance. Findings were typical of a maturation arrest in granulocytes. Chart 5 shows the drop in the total leukocytes with disappearance of granulocytes. We were unable to find any thiouracil chemically in the bone marrow, though a control normal marrow to which thiouracil had been added was positive. Twenty thousand units of penicillin was given intramuscularly every three hours. In addition, 6 Gm. of liver fraction L [3] was given orally daily, and a transfusion of 400 cc. of blood was administered. After three days the temperature fell to normal and as soon as the white count was normal the patient was discharged on the eleventh day. She is now being treated with Lugol's solution.

Case 6.—D. M., a woman aged 18, for three months, following appendectomy, had suffered from palpitation, nervousness, loss of weight, perspiration, diarrhea and slight prominence of the eyes. The basal metabolic rate was + 41. Thiouracil was given, 0.4 Gm. three times a day for two days and then reduced to 0.2 Gm. three times a day. On Oct. 20, 1944 there was a sudden onset of rash and fever of 103.5 F. with pains in the legs and swelling of the lymph nodes. Medication was stopped and an outside physician diagnosed a scarlatinal rash and administered sulfonamide drugs. The fever subsided in twenty-four hours and the rash in two days. On October 27 the patient telephoned that after two doses of 0.2 Gm. the same aches and pains and rash appeared, with a temperature of 101.5 F., which disappeared in twenty-four hours after stopping medication.

Case 7.—D. T., a woman aged 27, first noted nervousness, tremor of the hands and fatigue nine months before admission. At that time the basal metabolic rate was + 32. She was given iodine and in one month the basal metabolism dropped to + 18. In spite of this there was a persistence of nervousness, which became very evident and associated with "crying fits" and melancholia four months prior to admission. At this time iodine therapy was stopped, although the basal metabolic rate was found to be + 71. On no treatment there was a rise in metabolism to + 81, so that the patient was admitted to the hospital in November 1944. Enlargement of the neck was noted six months prior to admission and there had been a loss of 29 pounds (13 Kg.) since the onset of her illness. She was obviously malnourished on admission and psychotic looking. There were nervousness, tremor, perspiration and tachycardia. The thyroid was diffusely enlarged. There was slight prominence of the eyes. The basal metabolism was + 85. After one week of thiouracil therapy there was a drop to + 57 and after fifteen days to + 48. At this time there was a drop in the white count from 6,750 with 50 per cent polymorphonuclear leukocytes to 4,000 with 34 per cent granulocytes. The drug was stopped because of the granulopenia.

On theoretical grounds, thyroid hormone decreases the output of thyrotropin while a lack of thyroid hormone or a consequent lowering of the metabolism is considered to be a normal stimulus to the release of thyrotropin from the hypophysis. Therefore it would seem that excessive thyrotropin released through inhibition of the synthesis of thyroid hormone would result in exophthalmos or an exacerbation of that already present. Contrary to certain other observations, we found that exophthalmos never appeared in any case in which it was not present at the start of therapy and was, when present, not exacerbated by thiouracil. In the following 2 cases of malignant exophthalmos 1, in which thyroid and pituitary irradiation also were given, was unchanged, while the other, as a control, in which no therapy other than thiouracil was given, showed much improvement as demonstrated by the exophthalmometric measurements.

Case 8.—C. K., a man aged 24, a truck driver, was admitted to the hospital in 1940 when a thyroidectomy was performed because of nervousness, loss of weight, perspiration, weakness, diarrhea and progressive prominence of the eyes. The basal metabolic rate was + 50. Cholesterol was 125 mg. per hundred cubic centimeters. The pathologic report showed diffuse hyperplasia of the thyroid. On discharge, with the exception of slight tremor and exophthalmos, the symptoms and signs of hyperthyroidism had disappeared and there was a gain in weight of 8 pounds (3.6 Kg.). The basal metabolic rate was 0. In January 1941 the patient was readmitted because of a progressive return of the original symptoms, with loss of 17 pounds (7.7 Kg.) and an abscess in the scar, which was incised and drained. Examination at the time revealed hyperthyroidism with tachycardia of 110, diffuse swelling in the region of the thyroid, and a basal metabolic rate of + 45. On Lugol's solution the basal metabolic rate dropped to — 5. The thyroid region was explored, but no hyperplastic thyroid tissue was found. The swelling noted clinically was due to induration and fibrosis of the muscles and tissues of the neck. The symptoms then decreased but did not disappear. He was again admitted in August 1944 complaining of nervousness, loss of 40 pounds (18 Kg.), severe exophthalmos and enlargement of the neck. The basal metabolic rate was + 45 on admission, with cholesterol of 150 mg. per hundred cubic centimeters and blood sugar of 76 mg. per hundred cubic centimeters. Thiouracil therapy was instituted with a dose of 1 Gm. per day for seven days then reduced to 0.6 Gm. In spite of the severe exophthalmos, as a control for the next case, no thyroid or pituitary irradiation was given. The basal metabolic rate was reduced to + 5 in two weeks. There was a gain of 5 pounds (2.3 Kg.) and cessation of nervousness, tremor, palpitation and tachycardia. He was discharged on a dose of 0.3 Gm. This was continued for two weeks and the patient returned to work, the medication stopped. After one month without medication, the basal metabolic rate remained at — 3 and there was a gain of 17 pounds (7.7 Kg.) in weight. There was evident recession in the prominence of the eyes. On admission the exophthalmometric reading was right eye 28 mm., left eye 30 mm. On discharge it was right eye 24 mm., left eye 26 mm.

Case 9.—S. C., a man aged 27, had a thyroidectomy performed three and one-half years before the present admission because of tremor, nervousness, palpitation, loss of weight, enlargement of the thyroid and exophthalmos of six months' duration. Following this he received 10 minims (0.6 cc.) of Lugol's solution, three times a day for three years. The patient remained in good health with the exception of persistent and pronounced exophthalmos. Six months prior to admission Lugol's [illegible] and he promptly noted a recurrence of his symptoms. In the two months prior to admission, tremor and nervousness became very noticeable and he had frequent attacks of diarrhea. There was a loss of 20 pounds (9 Kg.) in this short period. A point of unusual interest is the occurrence of a rare symmetrical skin lesion in the legs which, clinically and on biopsy, proved to be localized myxedema. On admission the patient, with effort, was almost able to express both eyeballs from their sockets. The basal metabolic rate on June 27 was + 30 and on July 3 was + 32. The cholesterol on three occasions was 144, 140 and 138 mg. per hundred cubic centimeters, with blood sugar of 79, 78 and 70 mg. per hundred cubic centimeters. One Gm. of thiouracil was given daily over a period of ten days, following which the dose was reduced to 0.5 Gm. until discharge. The patient was ambulatory and received no sedation. Because of the severity of the exophthalmos, 0.03 Gm. of thyroid was given twice daily and pituitary irradiation every three days. On admission, exophthalmometric readings were right eye 31 mm., left eye 33 mm. and on discharge right eye 30 mm., left eye 31 mm., showing no increase in exophthalmos. The basal metabolic rate fell progressively to + 2, and there was a gain of 5¼ pounds (2.4 Kg.) and disappearance of all symptoms of hyperthyroidism at the end of the twenty-fourth day hospital stay. There was no change in the localized myxedema of the extremities

The two cases just presented would seem to indicate that even malignant exophthalmos is no contraindication to the use of this form of therapy.

A third case of recurrent hyperthyroidism is presented:

CASE 10.—S. T., a woman aged 35, married, had a thyroidectomy performed in October 1943 for thyrotoxicosis, as evidenced by enlargement of the gland, perspiration, exophthalmos and a basal metabolic rate of + 59. The pathologic report was thyroid hyperplasia. The postoperative course was uneventful and the symptoms and signs of the disease abated. Three months later all the previously mentioned symptoms had returned. Bilateral exophthalmos was present, more pronounced on the right side. The basal metabolic rate on June 16 was + 51. Cholesterol 150 mg. per hundred cubic centimeters, blood sugar 80 mg. per hundred cubic centimeters. The patient was given 1 Gm. of thiouracil daily for four days, then reduced to 0.6 Gm. until discharge. Within a week the patient stated that she was feeling less nervous. The symptoms gradually disappeared and there was a striking decrease in the size of the thyroid gland and a recession of the exophthalmos to the point where the eyes were no longer at all prominent. There was a gain in weight of 7 pounds (3.2 Kg.) and a fall in the basal metabolic rate from + 51 to — 3 in the thirty days of hospitalization. We had admitted the patient for a second thyroidectomy to compare our pathologic specimens but found the second operation superfluous. The patient has remained symptom free with a basal metabolic rate of + 9 on August 10, + 2 on August 24 and + 7 on September 7, on a maintenance dose of one 1 Gm. tablet every three days.

Thiouracil seemed to yield an excellent result in these cases of recurrent hyperthyroidism. In 2 cases there was palpable thyroid tissue, but in the third none could be found in the second operation. In some cases no definite thyroid tissue can be felt or found at operation. In these, as in the cases of deep substernal thyroid, use of thiouracil in the absence of intolerance is unquestionably the procedure of choice.

Thyrocardiac disease is the result of the increased circulatory demands on the heart due to the heightened basal metabolic rate and imposed on heart muscle whose metabolism has itself been altered like all other body tissues by thyrotoxicosis.

CASE 11.—M. P., a woman aged 38, married, was seen by an ophthalmologist five years before admission because of prominence of one eye, for which Lugol's solution was prescribed. There were complaints of nervousness, but the patient took Lugol's solution daily for four and one half years. Four months prior to admission she stopped taking this medication and began to lose weight. There were tremor, shortness of breath, perspiration and enlargement of the thyroid. There was no history of rheumatic fever. Examination revealed bilateral exophthalmos, an enlarged, somewhat nodular thyroid, the neck veins were engorged, and there was tachycardia, 140-150 per minute, with a heaving apical impulse. There was a systolic murmur at the apex, but no diastolic murmur could be heard at this time. There were rales at the base of both lungs. The liver was palpable five fingerbreadths below the costal margin. The spleen was palpable. On a dehydration regimen with digitalis therapy the signs of congestive heart failure decreased very slowly. Two days after admission a small amount of fluid was removed from the right pleural cavity. Five days after admission there was sufficient improvement to allow a basal metabolic rate determination, which was + 60. Cholesterol was 110 mg. per hundred cubic centimeters. At this time a definite diastolic murmur was heard at the apex and the cardiac contour revealed a general enlargement of the heart with prominence of the pulmonary conus. With barium in the esophagus a posterior displacement by an enlarged left auricle was noted. These findings, in addition to the later finding of elevation of the left bronchus, indicated the presence of mitral stenosis and insufficiency on a rheumatic basis associated with hyperthyroidism. It was the opinion of the observers that the patient had rheumatic heart disease and cardiac failure precipitated by the occurrence of hyperthyroidism. On July 22, ten days after admission, thiouracil therapy was begun with a dosage of 1 Gm. daily. This was continued for nine days and then reduced to 0.6 Gm. daily for eighteen days. During this time the subjective improvement was striking. Digitalis was stopped. The basal metabolic rate dropped to + 46 and then to + 35. There it remained at a fairly constant level for three weeks, during which time the dose of thiouracil was increased to 0.8 Gm. and then to 1.2 Gm. On September 8, fifty-four days after admission, the basal metabolic rate had dropped to + 30. There was no recurrence of congestive failure with the patient off digitalis during the last four weeks. Since there was a complete cessation of excessive perspiration, tremor, and a gain of 16 pounds (7.3 Kg.) with a normal pulse rate, the patient was discharged on a dose of 0.6 Gm. On October 16 the basal metabolic rate was + 10, the dose was reduced to 0.2 Gm., and on October 30 the basal metabolic rate was + 11.

CASE 12.—R. R., a woman aged 57, admitted with a history of nervousness, palpitation, profuse sweating and loss of 19 pounds (8.6 Kg.) in three years, with enlargement of the thyroid of several months' duration, had not been given Lugol's solution for five months prior to admission. The basal metabolic rate was + 55. The patient was given 1.2 Gm. of thiouracil for three days, the dose then being reduced to 0.8 Gm. for most of her hospital stay. There were attacks of palpitation during severe bouts of paroxysmal auricular fibrillation several times a day, lasting from one to two hours and causing the patient considerable distress. At the end of the first week the attacks of palpitation were found to be due to auricular tachycardia; there were no further attacks of paroxysmal auricular fibrillation. In addition, these attacks of tachycardia occurred less frequently. By the twelfth day they had disappeared completely and were replaced by extrasystoles. The patient still felt palpitation, but this was not as troublesome. At the end of the third week the extrasystoles were no longer present. During four weeks of hospitalization the basal metabolic rate was reduced to + 29. Signs of hyperthyroidism and the attacks of palpitation had disappeared and the patient gained 8 pounds (3.6 Kg.). After discharge the patient attended the follow-up clinic and on a dose of 0.6 Gm. daily the basal metabolic rate fell to + 16.

Since thyroid disease is one of the reversible types of heart disease, the toxic effect on the heart disappears with control of the hyperthyroidism. In case 1, as a result of thyrotoxicosis, circulatory failure was precipitated in a patient with mitral stenosis; as the thyrotoxicosis was controlled the patient improved, so that there was no recurrence of circulatory failure with physical activity for a period of weeks. In case 2 the gradually disappearing toxic effect was shown by the transition from attacks of auricular fibrillation to extrasystoles and finally a reversion to normal rhythm rate. The same result was obtained in both these cases that could have been accomplished by surgery, without the risks of thyroidectomy in cases of this type. In the first case there was some refractoriness to the drug; in the second the results were quite rapid. It is our opinion that as long as some improvement occurs thiouracil therapy should be continued, since some cases may be more refractory than others. In case 1, after the basal metabolic rate leveled off at + 40 after four weeks, it was suggested that no further result could be expected, but since the patient was doing well we persisted in using thiouracil therapy with ultimate success after eight weeks. This refractoriness of cardiac patients has been previously noted. It is of interest that there were no electrocardiographic changes in these or any other cases which could be attributed to direct action of thiouracil on the heart muscle.

There is some clinical evidence that the amount of diabetes, when present in patients with thyrotoxicosis, is a direct function of the basal metabolic rate. Total thyroidectomy ameliorates the coexisting diabetes. In Means's patient it was observed that as long as by withdrawal of thyroid she was allowed to remain myxedematous there was considerable lessening of her diabetes, but as soon as thyroid was administered her diabetes became intensified; when fully myxedematous she had no diabetes. The following 2 cases constitute a physiologic experiment of the same nature in reverse where, through administration and withdrawal of thiouracil, we were able to vary the intensity of the diabetes as measured by the insulin requirement. It would scarcely be possible to postulate the existence of a specific thyroid antagonism between the hormones of the pancreas and the thyroid, because the amount of diabetes may simply be the result of the decreased basal metabolic rate brought about by thiouracil.

CASE 13.—E. R., a woman aged 55, was admitted with a history of diabetes of five years' duration which had been

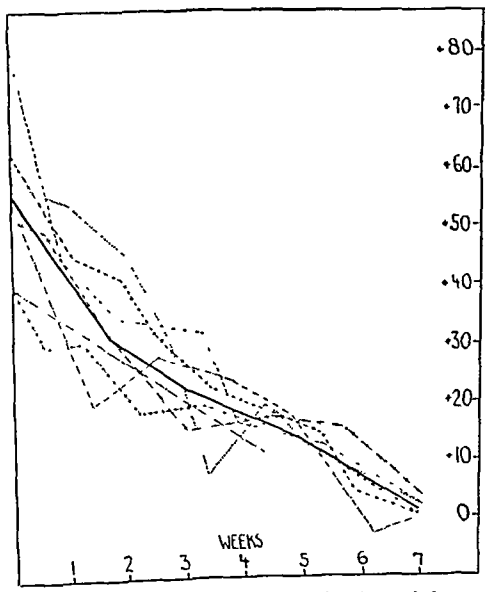

Chart 6.—A composite of the drop in the basal metabolic rate in first 8 cases treated with thiouracil. Average curves, the heavy black line, shows a drop of 1 unit in the basal metabolic rate per day.

controlled with diet and 60 units of protamine insulin daily. Enlargement of the thyroid gland was noted two years prior to admission. For several months she had complained of nervousness, weakness and loss of 15 pounds (6.8 Kg.). The diabetes was noted shortly after the menopause. Examination revealed agitation, slight stare, enlarged nodular thyroid and no tremor. The basal metabolic rate was + 40, the blood pressure 210/90, tachycardia 110 per minute. The urine contained 4 + sugar and traces of acetone. Blood sugar was 220 mg. per hundred cubic centimeters, cholesterol 256 mg. per hundred cubic centimeters. The patient was placed on a diet of carbohydrate 250, protein 80, fat 80, with 60 units of protamine zinc insulin daily. The urine became acetone free with 3 + to 4 + sugar. Four days after admission, thiouracil therapy was inaugurated with a dose of 1 Gm. daily for three days, which was then reduced to 0.6 Gm. until discharge. The basal metabolic rate gradually dropped over a period of two weeks to + 15, at which level it remained. There was general improvement in the diabetic status, so that with a constant diet the insulin was withdrawn by degrees until the patient received no insulin at all. The urine showed 1 + sugar with no acetone. The basal metabolic rate two months after discharge was + 12. There was a gain in weight of 6¾ pounds (3 Kg.). The subjective improvement in this patient was remarkable. Her family stated that she was a changed woman, no longer irritable but transformed into an energetic and useful woman. Objectively, all signs of hyperthyroidism had disappeared at discharge.

CASE 14.—E. K., a woman aged 55, weight 116 pounds (52 Kg.), was admitted November 15 with complaints of infection of the left leg of three weeks' duration. There was increased perspiration, swelling of the neck of one week's duration, nervousness, insomnia and loss of weight of 80 pounds (36 Kg.) in fifteen years. In addition, she had developed an infection of the left leg of three weeks' duration. She had had diabetes for thirteen years, of late controlled by 25 units of protamine zinc insulin and 15 units of regular insulin daily. The basal metabolic rate was + 33. The thyroid was enlarged, with a nodule in the left lobe. A systolic murmur could be heard over the precordium. The blood pressure was 190/90. The patient was placed on thiouracil 1 Gm. daily for three days, then reduced to 0.8 Gm. daily. After six days of thiouracil therapy her basal metabolism had dropped to + 18. At the end of ten days the regular insulin was stopped. Two days later the protamine was cut to 15 units, and at the end of two weeks all insulin was stopped. She is now under good diabetic control, on a diet of carbohydrate 250, protein 80, fat 80, with no insulin. The blood sugar is 183, with moderate glycosuria and no acetonuria.

It is well known that diabetes associated with hyperthyroidism is difficult to control. Improvement in the diabetic status goes hand in hand with improvement in the thyroid status. This has been frequently demonstrated by thyroidectomy and iodine. As would be expected, thiouracil yields similar results. As in cardiac patients, it would seem preferable to accomplish such a result by medical rather than surgical means, since the risks of anesthesia and operation can be avoided.

In our series of 96 cases of thyrotoxicosis treated with thiouracil, there were only 4 in which the drop in basal metabolic rate could not be fitted into the limits of the curve shown in chart 6. These were four severely ill thyrocardiac patients and the drop was distinct but the rate was slower. The median curve (heavy black line) shows a drop of 50 units in seven weeks. A rough rule may therefore be predicated that the basal metabolic rate will drop to zero in as many days as the height of the basal metabolic rate just before administering thiouracil. When medication had to be discontinued because of toxic effects of the drug, the fall in basal metabolic rate took place at the average rate up to the time of discontinuance of the thiouracil. Sixteen per cent of our patients are in sustained remission with no medication whatever for periods ranging from over two months to fifteen months after discontinuance of the drug. In 20 per cent thiouracil had to be discontinued because of sensitivity, and 9 of these were submitted to surgery without any untoward finding at operation. In fact, this drug is an excellent means of securing the lowering of the basal metabolic rate requisite for operation without necessitating any preliminary period of rest. There are 25 cases (26 per cent) in which the basal metabolic rate rises as soon as the maintenance dosage is lower than 0.2 Gm. daily. These have blood counts every three weeks, as outlined.

We have noticed an excellent response to the drug in young people who have had no previous treatment with iodine. The drop in basal metabolic rate is very rapid and the fall sustained. It is our opinion that thiouracil will find a wide field of application in these "fresh" cases as they occur.

CONCLUSION

Our results would seem to indicate that thiouracil will bring about a drop in the basal metabolic rate in all patients suffering from hyperthyroidism. It has, how-

ever, serious toxic effects and the patient must be kept under continuous medical observation so that the drug may be promptly discontinued and further injury to the patient prevented. The precautions to be observed are very similar to those employed for the careful administration of sulfonamide drugs. However, examination of the red blood cells is not necessary, as no injury to the erythrocytes has been noted. The main danger is agranulocytosis, and since we have noted a definite and sudden granulopenia in 20 per cent of our patients, it is apparent that a white blood count must be done every second or third day, and the drug must be stopped instantly if there is a sudden drop in the total leukocyte count, or if the granulocytes drop below 45 per cent. If there is a sudden rise in temperature, accompanied by arthralgia, myalgia, lymphadenopathy or the appearance of a rash, the drug must be discontinued. It is well to instruct the patient to inform any physician called in of the medication being taken so that sulfonamide drugs or other compounds containing the benzene ring are not prescribed. The patient should be given only two or three days' supply, just enough to last until the next blood count. Since this drop in the white count can occur with disconcerting suddenness at any time, it is doubtful whether thiouracil is as yet ready for long continued use in routine medical practice, until some method of protecting the bone marrow is perfected. The use of pyridoxine, vitamin B_6, in prophylactic doses of 150 mg. daily by mouth, or 200 mg. intravenously where a severe drop in the leukocyte count has taken place, seems at present to be most promising.

HERNIATION OF FASCIAL FAT AS A CAUSE OF LOW BACK PAIN

WITH RELIEF BY SURGERY IN SIX CASES

RALPH HERZ, M.D.
CLEVELAND

Eight years ago (1937) I observed a patient suffering from excruciating low back pain so severe that she was unable to get out of bed. Examination revealed a small tumor in the left sacroiliac region; pressure on this tumor intensified the pain. A biopsy was suggested, but the patient refused to have it done. Injection of 1 per cent aqueous procaine solution around the tumor gave temporary relief. Since then the patient has had periodic attacks of the same type of pain, necessitating bed rest. Injections of metycaine, strapping and physical therapy produced temporary relief.

In October 1943 another patient, also a woman, was seen because of acute low back pain, and she also displayed a small palpable mass over the right side of the sacrum, which was extremely tender and painful. Circuminjection with 2 per cent metycaine gave immediate relief. The patient had a history of "lumbago" of several years' duration. Often when she stooped she could not rise unaided, and during acute exacerbations she could not turn in bed. The patient agreed to a biopsy. On cutting down on the tumor, no demarcation was present, and it could not be differentiated from surrounding fatty tissue. Nevertheless, a wide dissection of fat was made in this area. When the patient emerged from anesthesia she volunteered the information that the pain in her back had disappeared, and she has remained free from it ever since.

This excellent clinical result was impossible to explain on the basis of any previous knowledge or experience. The pathologist's report was not enlightening. The specimen consisted of two similar lobulated masses of fat, roughly round and measuring 5 cm. in diameter. Sections showed homogeneous yellow fat, slightly lobulated. Around one surface there was a partial covering of loose but tough grayish brown fibrous connective tissue, apparently the seat of edema and hemorrhage. Microscopically there were lobulated groups of mature adipose cells separated by dense bands of fibrous connective tissue. In some places the latter showed edema and focal hemorrhage. The tissue was consistent with a pathologic diagnosis of fibrolipoma.

Within the next year 2 more women were seen with similar symptoms and similar painful, palpable masses. They also were subjected to surgical excision of the fatty tumor and experienced similar striking relief.

These first 3 patients who were operated on were all somewhat obese, and it was difficult in all to differentiate the mass from surrounding fatty tissue. Nevertheless excision of fatty tissue in the painful area afforded complete and immediate relief from the back pain.

The literature and anatomy textbooks were searched for an adequate explanation of the clinical results, but none was found until the article by Copeman and Ackerman [1] appeared. They reported 10 similar cases (all in men in the armed services) in which fatty tumors were excised, with striking relief. They also reported an anatomic study on 14 normal backs and showed that the palpable masses which are the seats of pain are herniations of fascial fat.

Since I have studied their report, I have operated on 3 additional patients, and the lesions undoubtedly are the herniations these authors described. In 1 patient the lobule of fat was discernible as soon as the incision was made (case 4).

ANATOMIC CONSIDERATIONS

Since the concept advanced by Copeman and Ackerman to explain the trigger points or "tender rheumatic nodules" of so-called fibrositis of the back offers an explanation for a condition whose etiology has been obscure, it seems worth while to present their findings in considerable detail.

The pain generally originates in certain focal points, from which more generalized subjective pain is referred segmentally. This referred pain may be at a considerable distance from its real origin, as in many cases of sciatica, in which the original focal point is in the lumbar or gluteal muscles. When these points are found by the palpating finger, the patient winces involuntarily. Pressure of the same intensity only a few millimeters away will not produce the same response. Pain referred to other areas from such a point will also generally be reproduced by this pressure. These trigger points tend to occur in certain predictable sites in the lumbar and gluteal areas and also throughout most of the dorsal area.

In the lumbar region the most common sites are at the edge of the sacrospinalis muscle just above the iliac crest, 1 inch above this level, and at the level at which the latissimus dorsi crosses the sacrospinalis. In the gluteal region points may be found all along the

Dr. Normand L. Hoerr, professor of anatomy, Western Reserve University School of Medicine, saw several of these patients before and after operation and discussed the findings during the investigation. Dr. Simon Koletzky of the Department of Pathology made the pathologic study of tissue removed at the operations.

1. Copeman, W. S. C., and Ackerman, W. L.: "Fibrositis" of the Back, Quart. J. Med. 13:37-51 (April-July) 1944.

crest of the ilium and for a distance of about 2 inches below it; also along the sacroiliac junction, where the deep fascia is attached. They are not commonly found elsewhere in the buttock.

Copeman and Ackerman dissected 14 backs, with special attention to areas which are the commonest sites of pain in so-called fibrositis. After one or two dissections their preconceived ideas of the importance of fibrous tissue were modified, as no fibrous lesions, abnormalities or adhesions were found at a deeper level than the subcutaneous tissues; and moreover it became obvious that the basic fat pattern, which persisted in even the most cachectic bodies, corresponded exactly with the pain patterns previously charted. Increasing attention was therefore paid in subsequent dissections to relationships of this fat and the fibrous tissues.

Beneath the subcutaneous fat and areolar tissue lies the highly vascular superficial fascia, which forms a continuous sheet from the neck to the gluteal region. Space between this and the deep fascia is principally potential, containing little or no fat. In certain well defined places, however, deposits of pinkish fat constantly occur. These, with equally constant deep areas, constitute the basic fat pattern. In obese persons this fat pattern tends to be obscured by more generalized deposition of fat. The fascias are not of uniform thickness, being notably thinner in certain places, and frequently there are actual deficiencies in the fascial membranes. In these places the underlying fat tends to bulge through, sometimes resulting in a complete herniation (fat hernia).

Detailed examination of synovial sheaths of all tendons and joints showed that they consist largely of rather fibrous fat, which forms a loose tunnel through which the tendon moves. As tendons are avascular and their microscopic structure does not suggest that they can readily become edematous owing to the dense nature of their constituent fibrous tissue, it is suggested that it is this investing fatty capsule which becomes edematous, thus narrowing the lumen of the tendon sheath and impeding its action, causing stiffness, which may ultimately lead to cessation of voluntary movement on account of pain.

In the lumbar region the sacrospinalis muscle is edged with fat, some lying superficial to the deep fascia (lumbar fat pad) and some lying within the angle made by the deep fascia as it splits to invest this muscle. In very wasted bodies this fat is deficient along the upper portion, where it lies under cover of the latissimus dorsi muscle. Below this strip the fat follows the line of attachment of the deep fascia and the muscle along the sacroiliac junction. Small fat hernias have frequently been observed in both these areas.

Although a majority of trigger points of pain in clinical subjects occurred at certain levels, these varied by about ½ inch on their horizontal plane. Dissection showed that this is due to variation in width of the sacrospinalis muscle according to muscular development. In the vertical plane, levels at which trigger points cluster most thickly are at the junction of the outer border of the sacrospinalis with the iliac crest 1-1½ inches above the crest, and 2-2½ inches above. Careful dissection at these areas, through the basic fat pad which lies in the superficial fascia, revealed that at these points the cutaneous branches of the posterior primary rami of the first three lumbar nerves pierce the deep fascia after leaving the body of the muscle. This they do through definite foramens accompanied by small blood vessels. There is a small horizontal fold of membrane, overhanging each foramen, which probably acts as a valve and prevents herniation of fat when the back is flexed. It is believed that these valves do not always perform this function efficiently, and failure to do so allows herniation to occur; this may result in lumbago.

It is not uncommon to find at intervals along the edge of the muscle small bubbles of deep fascia containing a few lobules of fat bulging up from the angle in which it is contained, and firm pressure can easily convert it into a true fat hernia. These small hernias tend to occur at points where the fascia is weak and do not give rise to symptoms until some incident, such as sudden trauma or some pyrexial illness which entails lying on the back for several days produces an increase in the fat pressure and a painful degree of distention. This leads to edema, which may perpetuate the condition.

In the gluteal region there is a crescent of pink fat, extending along the crest of the ilium and for about 2 inches below. It is contained within the superficial fascia and extends from the anterior superior spine back to the sacroiliac junction, often sending a narrow prolongation down this area. A similar tongue of fat lies in this region, but at a deeper level, being contained in the angle of the deep fascia. It is thus continuous with the fat along the edge of the sacrospinalis muscle in the lumbar region.

The fat along the iliac crest lies in layers, where it has split the superficial fascia in which it is contained, and it is common for lobules of one layer to herniate into a more superficial layer, or laterally into an adjoining compartment, where the fibrous walls are weak or deficient. The fact that this pad of fat lies almost directly over the unyielding bone of the ilium may account for the common occurrence of such lesions in this area.

PATHOLOGIC CONSIDERATIONS

The anatomic study by Copeman and Ackerman showed that trigger points of pain in the back apparently have a topographic relationship to the basic fat pattern. Herniation of fat lobules through fascial weaknesses, deficiencies or foramens was found in dissection, and such herniations were proved to be sites of pain in living patients. They differentiate three types of fat hernias: nonpedunculated, pedunculated and foraminal.

Fat which lies under a fascial covering, as in the angle of the deep fascia where it splits to invest the sacrospinalis muscle, or along the crest of the ilium, is always under tension and so will bulge into any potential hernial space, as the result either of congenital weakness or of trauma. This tendency will be increased by muscular action. Such potential hernias probably should not be considered pathologic unless they cause congestion and pain by constriction of enclosed fat. In this case edema and hemorrhage may have occurred which, by increasing the tension, initiate a vicious circle and so in time tend to make the condition chronic. In microscopic sections from biopsy specimens some degree of commencing fibrosis has also been seen, suggesting that if such a hernia is subjected to chronic "strangulation" for a sufficiently long period it might be converted into a true fibrous nodule, though this has not been observed.

Nonpedunculated hernias were most commonly found in the lumbar fat pad, lying within the superficial fascia and in its extension downward along the crest of the ilium, in the gluteal region. These tense swollen fat nodules were palpable when sufficiently superficial. A

variant of this type is that which protrudes in a horizontal direction, the contents of one fibrous compartment herniating through an imperfection in the wall of the neighboring compartment as the result of some extra tension; this type occurred most frequently along the iliac crest.

The authors found no instance of pedunculated hernias in normal backs dissected, but several were found and removed in patients subjected to operation. In each of these cases there was sudden onset of pain produced by a strain several years previously. Hence it is thought that this type probably is a late result of strangulation in a hernia originally of the nonpedunculated type. The appearance is similar to that of an ordinary pedunculated polyp, but a lobule of fat replaces the terminal polypoid tissue. This polyp lies in a layer of fat more superficial than that from which it springs, being connected with its roots by a pedicle which generally contains fibrous tissue and a blood vessel. The pedicle sometimes appears to be twisted. Histologically there is generally some fibrous tissue merging into the terminal fat of the lobule.

Copeman and Ackerman also report a foraminal type of hernia found only along the edges of the sacrospinalis muscles, supplied by the lumbar nerves, in the first, second and third of which the lateral branches of the posterior rami become cutaneous and pierce the deep fascia at the spots where trigger points of pain chiefly occur. In several cases a herniation of this type was found to be the cause of sudden lumbago, and removal of the edematous fat and enlargement of the foramen proved curative.

Of the 6 cases presented in this report, not one of the foraminal type was seen, and only one of the fat lobules removed had a discernible pedicle. Histologic findings were similar to those described by Copeman and Ackerman. They report that microscopically the nodules removed at operation consisted principally of fatty tissue with young cellular fibrous tissue growing into it. The blood vessels were congested and their walls thickened, with perivascular proliferation. There were also in some nodules occasional patches of older fibrous tissue. In 1 case there were lobulated groups of mature adipose cells separated by dense bands of fibrous connective tissue, which in some places exhibited edema and focal hemorrhage. In 1 (case 6) nerve tissue was found in the fat lobule, with edema and focal hemorrhage. In other cases the specimen consisted only of fat tissue showing edema and hemorrhage.

CLINICAL CONSIDERATIONS

In all 6 cases in this series there was a history of trauma due to strain which had initiated the pain. Pain in the back was extremely severe in all and in some instances was referred down one leg. Two patients had had recurrent attacks of acute lumbago for fifteen years which had been incapacitating and required bed rest. One could not turn in bed during these exacerbations. In all cases a definite mass was palpable which was extremely tender and pressure on it intensified the pain. Injection of these masses with procaine or metycaine solution provided temporary relief in all instances. In 1 instance the condition was bilateral, although the symptoms were more severe on one side.

Important diagnostic features are the severity of the pain, the frequency of radiating pain down the leg, the presence of a palpable tender mass which is a "trigger point" of the pain, which can be relieved temporarily by injection with anesthetic solution. This condition may be present with other diseases, such as pelvic disorders, to which the back pain may be erroneously attributed. One patient in this series had had fibromyomas of the uterus for which hysterectomy had been performed, but severe attacks of back pain had continued and had not been relieved until the fascial fat hernia was removed.

It is my impression that some, and perhaps many, of the cases of so-called functional back pain, which is considered to be psychogenic, may be due to fascial fat hernias. Whenever one makes a search for psychic disturbances they are quite easy to find in almost any patient, but my experience convinces me that they are seldom, if ever, the cause of excruciating pain in the back.

From a surgical standpoint, removal of the palpable fat mass presents some difficulty, especially when there is considerable superficial fatty tissue. In the first case in which operation was performed, a wide dissection of fat in the painful area relieved the pain immediately and permanently. In subsequent operations the palpable mass was transfixed with needles before the incision was made, a procedure which Copeman and Ackerman also used. In the first 3 cases in this series it was not possible to see a definite mass that could be clearly differentiated as the palpable nodule. As already mentioned, these patients were relatively obese women, which undoubtedly accounts for at least part of the difficulty. It was also occasioned by a lack of knowledge as to the type of lesion being sought. In the fourth operation, on dividing the superficial fat and retracting the edges of the wound a fat tumor popped into the wound. In this and the subsequent instances, operations were performed with more assurance, since it was known that the lesion would be a lobule of fat, as proved by the three previous operations and the elucidation of the condition in the article by Copeman and Ackerman.

COMMENT

Since all the patients so far operated on were women, I thought at first that perhaps the condition was confined to females or at least more prevalent in them. However, all 10 cases reported by Copeman and Ackerman were in men. Recently I saw a man with severe lumbago who had several palpable nodules that were trigger points of pain; injection of these with metycaine solution has provided temporary relief. It would seem that in civilian practice the condition may possibly be more prevalent in women, since with their inferior muscular development a less severe strain may cause herniation of fascial fat. It also seems likely that the lesion may be more difficult to discern at operation in women because of their greater superficial fat padding.

In these 6 cases fairly wide dissection of fat in the painful area has relieved the pain, whether or not the herniation could be clearly delineated. One or more lobules of fat were removed in all the cases reported by Copeman and Ackerman. They also describe a technic which they call "teasing" the nodule which produces more lasting results than ordinary injections.

REPORT OF CASES

CASE 1.—A married woman aged 30 had had recurrent symptoms of lumbago for fifteen years. She always had to be careful when she stooped or lay down, for she was prone to get a "catch" in her right leg and would have to have some one pull her to an upright position. She had noticed a minute tumor over the right sacral region, which she thought had been present throughout the period in which she had had diffi-

culty with her back. Examination revealed a small mass over the right side of the sacrum. Circuminjection with procaine solution afforded temporary relief from the pain.

At operation a transverse incision was made over the fifth right lumbar area and carried down through the subcutaneous tissues. Bleeding points were clamped and ligated with plain number 1 catgut. A firm nodule and its surrounding tissues were widely excised. Comparatively little bleeding was encountered. The skin was closed with silk sutures.

The pathologist's report on the tissue removed was that it consisted of two similar lobulated masses of fat, roughly round and measuring 5 cm. in diameter. Sections showed homogeneous yellow, slightly lobulated fat. Around one surface was a partial covering of loose but tough grayish brown fibrous connective tissue which appeared to be the seat of edema and hemorrhage. Microscopic examination showed lobulated groups of mature adipose cells separated by dense bands of fibrous connective tissue. In some places the latter showed edema and focal hemorrhage. The tissue was consistent with a clinical diagnosis of fibrolipoma.

As soon as the patient recovered from the anesthetic she remarked that the pain in her back and leg was gone, and she has been entirely free from it since operation, eighteen months ago.

CASE 2.—A woman aged 67 sought medical attention because of a severe pain in the back which had appeared as she was getting out of bed; she had had similar attacks before. At examination a painful nodule was discovered in the right sacroiliac region; this was relieved with injection of 2 per cent procaine solution. Before operation the painful tumor was transfixed with two needles. An incision about 3 inches long was made over the tumor and wide dissection carried out to the fascia of the sacrospinalis muscle. A portion of the fifth lumbar nerve about 2 inches long was dissected and removed. The wound was closed with interrupted silk sutures, and sulfathiazole powder was applied. This patient also experienced complete relief immediately after operation. It has been impossible to follow her progress since.

CASE 3.—A woman aged 50 complained of pain in the back and along the back of the left leg, which had been present two months and had become exceedingly severe during the last week. A palpable nodule was found in the left sacroiliac region; this was relieved by metycaine injections. Under 2 per cent procaine infiltration anesthesia an incision was made just lateral to the left sacroiliac joint down through the fatty tissue. With a combination of blunt and sharp dissection a mass of fatty tissue was excised. The specimen consisted of three similar irregular masses of yellow adipose tissue measuring 1, 1.8 and 4 cm. in longest diameter respectively. Cross sections were homogeneous except for foci of hyperemia and hemorrhage. Microscopic sections showed fragments of fat, with edema and focal hemorrhage; there was no inflammation or necrosis. Pain in the back was completely relieved, and there has been no recurrence in the nine months since.

CASE 4.—A woman aged 48 had been struck by a 2 by 4 plank in the left buttock eighteen years previously and had had a "weak" back ever since. Two years before, the pain had become appreciably worse. Osteopathic treatments had afforded no relief and she had spent more time in bed than out during this period. The last two weeks the pain had become unbearable. When she was standing or walking the pain seemed to advance from the heels over the calves and thighs into the back. She was carried into the office for examination, which revealed a nodule in the left gluteal region. This was circuminjected with 2 per cent metycaine solution. The pain subsided promptly and the patient was able to get up from the couch and walk out of the office unaided. Injection of the nodule was done again twenty-four and forty-eight hours later, at which time she was hospitalized for operation.

An incision about 4 inches long was made over the fatty tumor in the left sacroiliac region about 2 inches below the iliac crest. On division of the superficial fat and retraction of the edges of the wound a fat tumor about 2 cm. in diameter popped into the wound; this was densely adherent to fascia of the gluteal muscles. It was dissected with sharp dissection and excised. After it was removed, another tumor about the same size appeared in the wound; this was also removed by sharp dissection. Exploration revealed no additional tumors.

The specimen consisted of two similar small roughly round masses of homogeneous lobulated yellow fat measuring 2.5 and 4 cm. in diameter. Both were composed of homogeneous adipose tissue showing focal edema and hemorrhage; there was no inflammation.

The patient had complete relief from pain when she emerged from the anesthetic.

CASE 5.—A woman aged 42 was first seen in November 1944 complaining of back pain and pains in the legs of more than two months' duration. She had been under the care of another physician and had been hospitalized for complete examination but had been dismissed without a definite diagnosis and with the pain persisting. My own examination at that time did not reveal a definite mass, and the diagnosis was indefinite. This attack subsided, but the patient consulted me again in March 1945, after having suffered an exacerbation of the pain for five weeks. At this examination a definite tumor was palpated in the left lumbar region, and pain was relieved by injection of metycaine solution.

At operation an incision about 4 inches long was made about 2 inches below the crest of the ilium. A herniation of fascial fat was located and excised, with some surrounding fatty tissue. The pathologic diagnosis was fatty tissue, herniated tumor. Pain was absent when the patient emerged from the anesthetic and she was out of bed, walking, the following day.

CASE 6.—A woman aged 51 sought relief from low back pain at a time when she was having an exacerbation of excruciating pain. She had had pain in the lumbosacral region, radiating into the groin and thigh, especially on the left side, with periodic exacerbations of severe agony. Roentgenograms recently made at an osteopathic clinic had shown calcium deposits in several vertebrae but no lesion in the sacroiliac region. Tender masses were found on both sides of the spine in the sacroiliac region; circuminjection of these produced prompt relief of pain.

The diagnosis was bilateral herniations of fascial fat. At operation a 4 inch incision was made over each mass. Hernial openings in the fascial membrane were found and the herniated fat was excised on both sides. Each hernial opening was closed with three interrupted sutures of chromic number 1 catgut. The skin was sutured with number 30 alloy steel wire, and sulfathiazole was applied to the wounds. Immediately after operation the patient experienced complete relief.

The pathologist's report was as follows: The specimen consisted of two similar flat masses of yellow adipose tissue meauring 3 and 3.5 cm. in diameter and a few millimeters in thickness. The outer surfaces were slightly nodular and covered in part by strands of pale gray firm connective tissue. Cross sections showed homogeneous fat. Also present were eleven separate similar small fragments of yellow lobulated fat measuring 1 to 1.5 cm. in diameter. Cross section showed that the strands of connective tissue partly lobulated the adipose material.

Microscopic examination of the specimen removed from the left side showed mature adipose tissue supported by numerous strands of dense collagen. Focal edema and hyperemia were present, but no exudative change. In some places small nerve fibers and nerve trunks were observed in the collagenous stroma. The specimen from the right side consisted of mature fat with only a small amount of fibrous connective tissue. Edema, focal hemorrhage and hyperemia were present, but no inflammation was found. No nerve tissue was identified in the second specimen.

The pathologist's diagnosis was fibroadipose tissue, the seat of edema and hyperemia (region of the left buttocks), and adipose tissue, the seat of edema and hemorrhage (region of the right buttocks).

SUMMARY AND CONCLUSIONS

In 6 cases excruciating pain in the back, sometimes accompanied by leg pain, was relieved by removal of a herniated tumor of fascial fat. In all instances there was a palpable mass which proved to be a trigger point

of pain, and the diagnosis was confirmed by injections of anesthetic solutions around the mass, which produced prompt though temporary relief.

Since pain in the back is such a common cause of disability, any light that can be thrown on any of these cases is valuable from the clinical standpoint. There are many known causes of back pain for which there are standard treatments, but there are also many cases in which the cause is obscure and the patient gets little or no relief from symptomatic treatment. In some cases severe pain in the back is attributed to psychic disturbances. It seems probable that some patients (perhaps a fairly large proportion) in whom the cause of back pain has not been diagnosed previously may have herniations of fascial fat and that surgical removal of these will bring prompt and lasting relief. This operation is not presented as a panacea for all types of low back pain. However, it seems certain that if the possibility of such a lesion is recognized and if careful examination is made for palpable masses which may prove to be trigger points of pain, numerous patients may by this procedure be relieved of a condition that has been incapacitating, sometimes for many years.

1990 Ford Drive, Cleveland 6.

CALLUSES, CICATRICES AND OTHER STIGMAS AS AN AID TO PERSONAL IDENTIFICATION

FRANCESCO RONCHESE, M.D.
PROVIDENCE, R. I.

From Ramazzini to the modern outstanding works of Oppenheim,[1] Natori,[2] Prosser White [3] and Schwartz and Tulipan [4] much has been written on the subject of professional stigmas.

Many investigators have been interested particularly in a rapid detection of a person's occupation or business by a glance at his palms, by his general appearance, by the odor emanating from his body or clothes, and so on. For instance Tardieu,[5] in his lengthy paper published almost a century ago, tells of the pride of Corvisart, Dupuytren and Trousseau in announcing the patient's profession at first sight.

The present study is an attempt to assemble examples of stigmas, some characteristic and common, valuable for identification purposes, some uncommon or rare or obsolete, of much less practical value but interesting.

Most of the observations were made on private or hospital patients seeking various forms of medical care. Inevitable omissions and errors are due to the difficulty of covering all trades or professions, to the ever changing ways of doing the same kind of work, to the machine substituting for man, giving him a handle to grasp or a pedal to press instead of employing his fingers, to the use of gloves or other protecting devices, to the variety of works using the same tools and producing the same calluses, and to the disappearance of some of them soon after the work is discontinued. Hence a characteristic stigma has a positive value when found, but a trade or profession cannot be ruled out when it is not found.

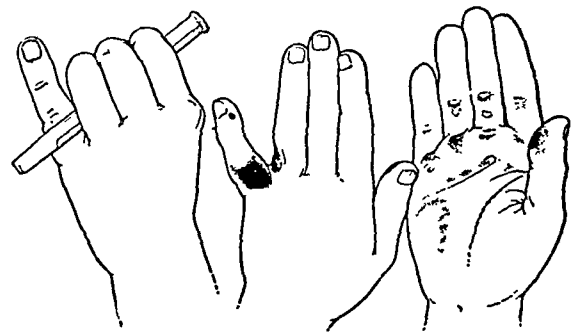

Fig. 1.—Location of the stone cutter's "ring."

A stone cutter can use heavy gloves, and the characteristic callus on his little finger (figs. 1 and 2) may be missing. A tailor may show only needle marks on his left index finger tip, if he is a sewer, or only a heavy callus on his right thumb, if he is a cutter.

There are manual laborers with unmarked hands because of the use of gloves, and intellectuals with laborers' hands because of sporting or laboring hobbies.

Fig. 2.—The stone cutter's "ring," one of the most characteristic examples of a stigma helpful for personal identification because exclusive of the stone cutter or maker of funeral monuments or curb stones, *mostly* using the mechanical chisel resting on the little finger.

A small number of trades or professions leave characteristic, unique, unchallengeable stigmas.

The skin has been called the monumental façade of the human body telling the age, the peaceful or

calamitous past, the effeminate or virile character, the constitution of its bearer.[6] The hands are an important part of the revealing monumental façade. They may record what the face may conceal. The warm and dry handshake, the cold and clammy handshake, the clasping and twisting and biting of one's hands in an effort to control one's emotions, the opening of the same hands in a state of peace and relaxation, the gesture in conversation or public speaking are revealing psychologic characteristics. Material past and present are revealed by the professional marks (calluses, scars, pigmentations, tattoos and the like). Illnesses (such as cachexia, hemiplegia, arthritis, parkinsonism, pellagra and thyrotoxicosis) leave distinctive signs. Besides the dead, identification may be useful in the living, in cases for instance of amnesia or of unsatisfactory fingerprints.

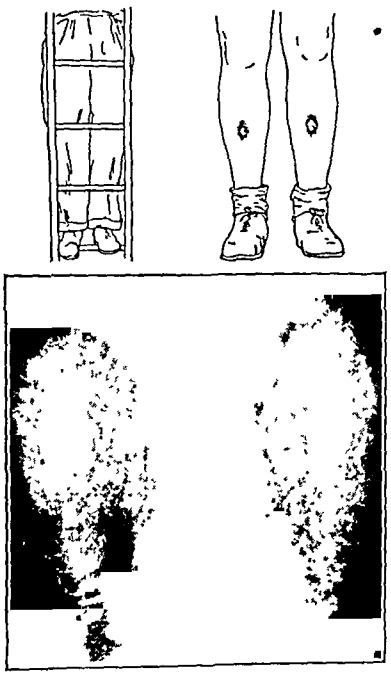

Fig. 3.—The painter's calluses, an elongated yellowish swelling about the middle of both shins from pressure on one rung of the ladder on an area practically without subcutaneous fat: a good professional stigma. However, it can be found in carpenters doing some painting, in maintenance workers in any factory, in electricians and, in general, in a worker standing for a certain length of time on a ladder.

Fingerprinting is considered the infallible method of personal identification. However, besides the cases in in which no fingerprints had been previously recorded, or the case of the criminal having a plastic operation done, there are cases in which fingerprints are unsuccessful, temporarily or permanently. For instance, in diseases of the skin, such as acute or chronic eczema involving the fingertips, there is peeling or cracking or smoothing out of the fingertips sometimes so severe that the remnants of papillary lines may be useless for fingerprinting purposes. This is, or may be, only a temporary occurrence, but it is a frequent one. Just consider how common is eczema of the fingers and one can figure out how often fingerprinting may fail. In chronic diseases of the skin, as in scleroderma, Raynaud's disease and Darier's disease, the absence of fingerprinting possibilities is permanent.

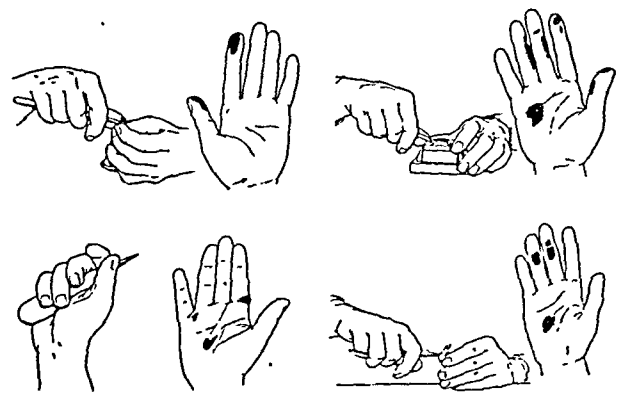

Fig 4.—Most common calluses of the jeweler engraver's profession.

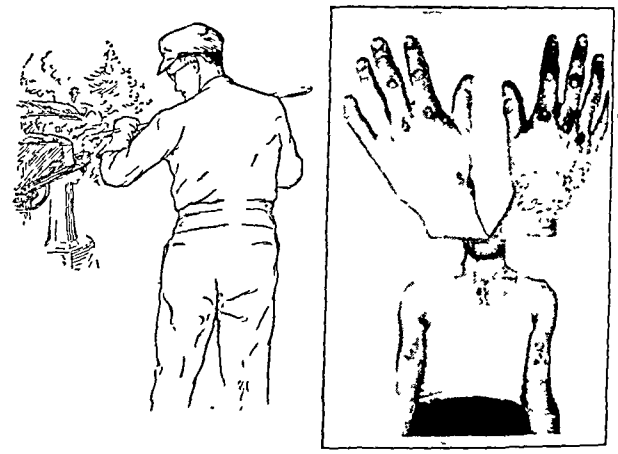

Fig. 5.—Quite characteristic stigmas of the optical glass molder. In spite of gloves or clothes, knuckles and arms receive repeated burns while standing in front of small ovens heated to 2300 F. Scars may also be found on dorsa of feet from dropping molten material.

Transitory absence of papillary lines is found in workers handling heavy and rough metal parts (steel, file, bricks), in pottery workers and in marble polishers. Some of the workers remark that they are free to commit a crime because their fingerprints will not identify them. This absence may, of course, be for short duration. In fact, papillary lines are promptly reformed as soon as work is discontinued. But if a worker is killed at work and his body lies unidentified and no help is to be obtained from his fingertips, other means of identification may become useful. This is the case in which professional calluses, worn out fingertips or scars may supply the identifying clue.

Fig. 7.—The junk worker or dealer shirs. A good professional stigma, found in a lesser degree in railroad conductors or engineers, garbage collectors, firemen, truck drivers, foundry workers and others.

Ribeiro,[7] a pioneer in the study and demonstration of the shortcomings of fingerprinting, has demonstrated in several publications the cases of Brazilian convicts fingerprinted successfully in their youth; but fifteen to twenty years later this was useless

7. Ribeiro, Leonidio: Dáctilo diagnose (contribuição da medicina legal para a propedêutica medica), Rio de Janeiro, Imprensa Nacional, 1939.

because of the damage done to the papillary lines by leprosy. He even published the report of a case in which the altered papillary lines led to the diagnosis of leprosy.

Textbooks of dermatology and forensic medicine, very meager in text and illustrations on stigmas from trade or profession, do not even mention diseases or conditions making fingerprinting useless.

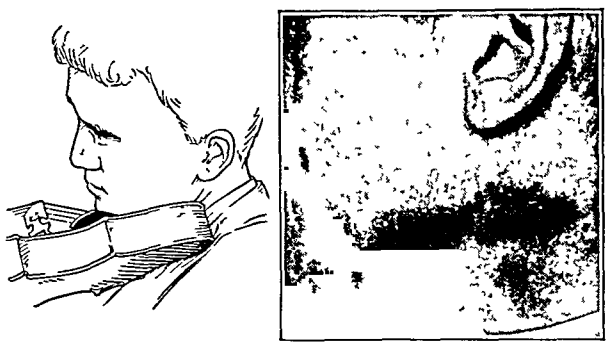

Fig 8.—The acneform dermatergosis of the violin or viola player, an exclusive stigma of the profession. A rather small percentage of violinists show a stigma as conspicuous as the one in the illustration. Generally it is found in players of the thin, pale, feminine type.

The odor emanating from clothes or the body may help considerably in determining the social status, the profession and the ancestry. Characteristic odors can be detected in bartenders permeated with the peculiar smell of the bar room, in incinerator workers and ash collectors from ashes, in doughnut dough mixers from vanilla, in tanyard workers, butchers, sauerkraut packers, fertilizer manufacturers, fish dealers or fishermen, stable hands, sewage farm attendants or dish washers,

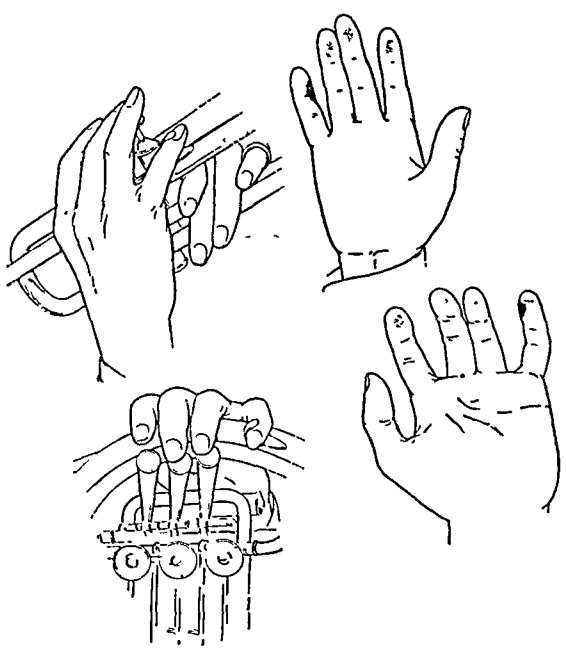

Fig. 9.—Above, callus on right little finger of the trumpet or tuba player. Below, callus on left little finger of the French horn player.

from the material contacted, from perspiration and from general habits of uncleanliness.

A characteristic odor emanates from grocers handling special types of food. For instance, persons working in Italian grocery stores where strong cheeses and peculiar smelling seasoning spices are handled all day emanate a distinctive odor from their clothes.

The odor of tobacco from cigarets, cigars or a pipe has little importance for personal identification, because

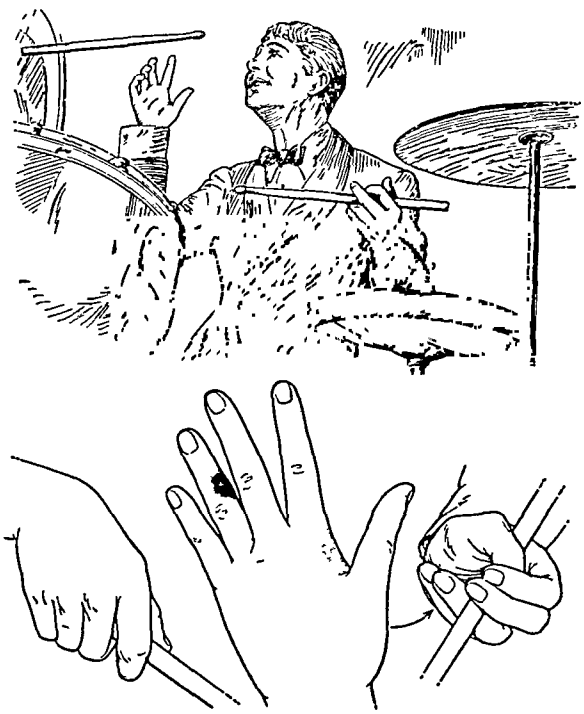

Fig 10.—Characteristic and peculiar callus of the jazz band drum player

Fig 11.—Cauliflower ear of the boxer-wrestler. With it goes a cracked nose, dislocated thumbs, a blind eye, eyebrow scars and the body build of a male fighter (female boxers are still rare). (Courtesy of Alfred A. Monner, Portland, Oregon.)

practically everybody indulges in one or all of them. However, when certain types of cigars are used by a relatively small percentage of the population, of one ancestry, the finding of those cigars and the odor emanating from the clothes or impregnating the room may be of diagnostic importance in the determination of the same ancestry. While others than Italians may occa-

sionally smoke a stogie, it can be safely stated that, when one sees one of those hard, thin, black, smoking sticks in a man's mouth, or if it is found in a man's pocket, the man is not only of Italian ancestry but almost certainly a native of Italy.

The color, besides the race, may give a hint of the occupation. Workers in contact with coal tar and petroleum derivatives show melanosis of the exposed

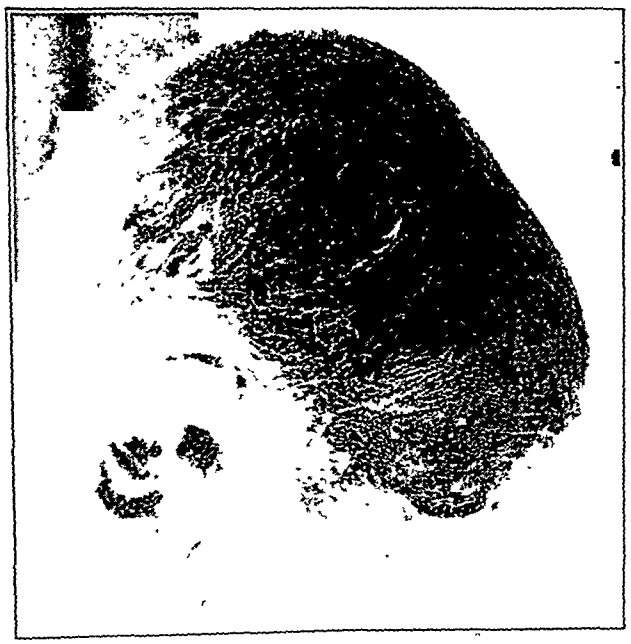

Fig. 12.—The peculiar scarry alopecia and the sparse coarse hair on the sides of the head of a commonly bald man, remnants of tinea favosa suffered during youth. This is common in Europe and rare in this country. Consequently its bearer is most likely of European birth.

parts and eventually cancer from photosensitization. Silversmiths may absorb so much silver as to become slate gray. Explosive powder workers, called "canaries," can be recognized in the street because of a

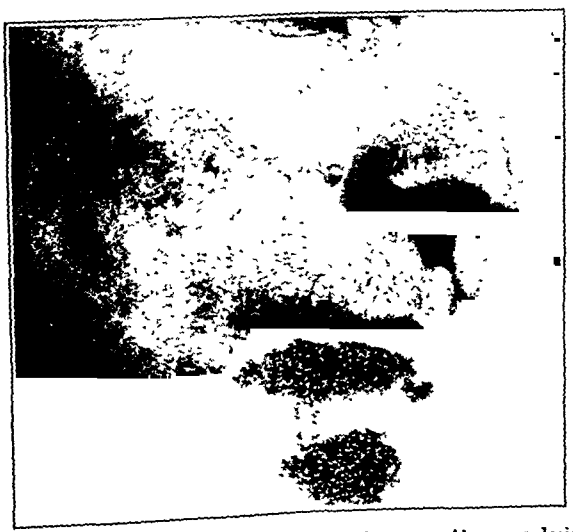

Fig. 13.—The scar of the so-called oriental sore or Aleppo or Jericho boil. A cutaneous lesion from Leishmania tropica, improperly called a boil. A characteristic stigma found practically only in persons of Armenian birth, in lesser number in Syrians and in general in natives of Asia Minor.

peculiar red-yellowish stain of hair and skin from tetryl. Workers with explosives may show deep yellow stains and exude the odor of picric acid. Yellow stains on the fingers can be found in laboratory workers from the xanthoprotein reaction of nitric acid, in jewelers from cyanides, in canners of pickles, in inveterate cigaret smokers. Photographers, shoemakers and shoeshiners show black stained nails. Electric bulb cleaners show a black discoloration of the nails from hydrochloric acid.[8]

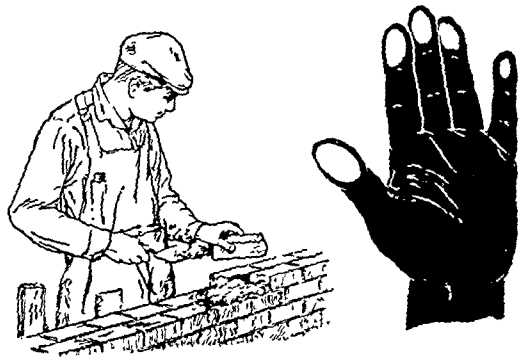

Fig. 14.—The left finger tips of a mason. Unless left handed, he grabs the rough brick with his left hand. His left finger tips are worn out, shiny, often bleeding, a valuable stigma for occupational identification. Satisfactory fingerprints may not be obtainable from the left hand. A similar condition may be found in file workers as the result of handling the rough surfaces and the heat of the files and in handlers of heavy metal parts

A peculiar depigmentation of the forearms in Negro tannery workers has been reported by Oliver and Schwartz[9] from an antioxidant added to the rubber of the gloves. Cleaners using oxalic acid show blue discolored fingers. Furniture polishers show reddish discoloration of the nails and shiny, worn out nails.

Age can be fairly well estimated from the color as well as texture in the so-called farmer or sailor or fisherman skin and from the middle age and old age spots popularly associated with the liver.

The hobo's "profession" can be recognized in a body covered with papules, pustules, scars, hyperpigmentations and depigmentations, characteristic of the so-called vagabond's disease.

Stigmas peculiar to a person's occupation are due to pressure, friction, repeated injuries and joint deformities.

Many diffuse palmar calluses begin with painful blisters, gradually replaced by the calluses which allow the continuance of the work without much discomfort.

Calluses may be so thick and hard as to be better labeled corns. Other body marks are the telangiectases,

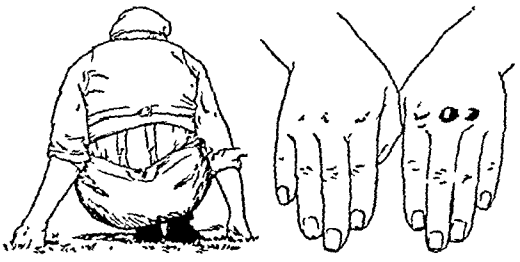

Fig. 15.—Landscape gardener leaning on fisted left hand while cutting grass with the right. The pressure of the leaning body produces knuckle calluses, particularly thick on the carpometacarpal knuckles of the left middle and ring fingers.

pigmentations, scars and eventual epitheliomas from repeated exposure to heat or burns, and tattooing seen in coal miners, together with pneumonoconiosis, in silversmiths and in file workers, or from intragluteal injections of mercury sulfide, a sign of antisyphilitic treatment. Scars are often characteristic of the man's

9. Oliver, E. A.; Schwartz, L., and Warren, L. H.: Occupational Leukoderma, Arch. Dermat. & Syph. 42:993 (Dec.) 1940.

occupation, the classic ones of the shoemaker's knife on the right thigh, for example.

The importance of tattoo marks for identification purposes is well known. In fact, the tattooed often give identification as a reason for doing it.

Besides the actual name or initials of the owner, battleships, flags, knots and naked or seminaked women point toward the sailor's profession. Occupational signs, as a hammer or a razor, indicate the profession of carpenter or barber. Obscene figures and mottoes suggest a criminal or a prostitute. Tiny flowers, butterflies, united hearts, chains, artificial beauty spots, ruby tattooed lips suggest the body of a female.

Specialists in tattooing can recognize from the technic employed where the work was done and eventually identify the nationality of the tattooed.

The hand of the laborer shows characteristically rugged, leathery, thick, yellowish palms and rough, reddish brownish dorsa from the sun, the wind, the heat, the cold and the repeated injuries, and thick knuckles from repeated knocks. If past middle age, his dorsa will show the keratoses of the so-called farmer or sailor or fisherman skin, the forerunners of cancer.

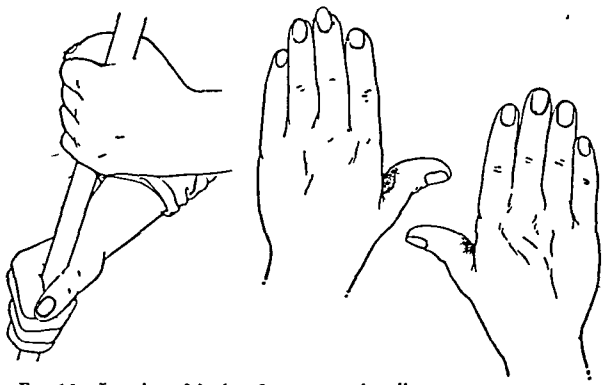

Fig. 16.—Location of janitor floor sweeper's callus.

Stone chiselers (the maker of monuments, sidewalk stones, building bases, marble ornaments) have a most characteristic mark of their profession, a large, soft rubbery callus at the proximal end of the left little finger (figs. 1 and 2).

Painters and paper hangers have a very distinctive elongated callus exactly on the center of both shins (fig. 3) resulting from the continuous pressure of one rung of the ladder on an area practically lacking subcutaneous fat.

Jewelers, engravers, ring makers and stone setters have as their most important tool the "plier," which produces a characteristic large and heavy callus in the center of the right palm (fig. 4). Other calluses also quite characteristic of the jeweler's profession differ according to the particular kind of object manufactured.

Machinists, mechanics and tool makers have in general rough hands and deeply cut and scratched, worn out nails, worn out and bleeding finger tips and palms studded with particles of steel from handling and filing rough and heavy steel parts. Machine oil, cutting oil and soda water do their part in roughening the hands of mechanics.

The handling of materials coming from highly heated ovens as in foundries and by optical (fig. 5). knife, file and incinerator workers produces heavy, painful calluses and deep fissures often necessitating discontinuance of work until the tissues are returned to a fair condition.

An interesting stigma can be observed in most foundry workers, feeders of large boilers and melters of metals. A forearm may be exposed continuously to such an intense dry heat in the procedure of pulling hot materials from the ovens that a red streak remains to tell the tale. Only a few spots show scar tissue.

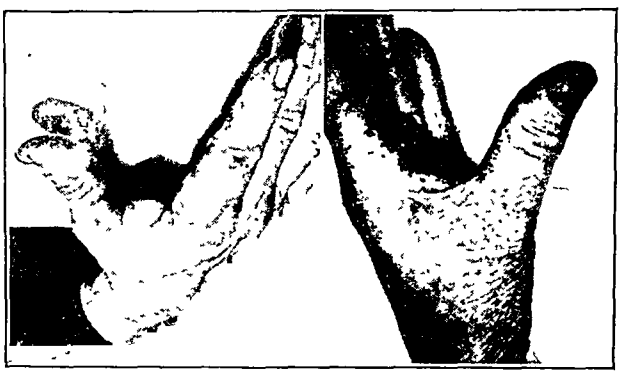

Fig. 17.—Janitor-floor sweeper's callus. Illustration at right shows an epidermoid carcinoma of grade 2 in a 50 year old woman, very likely an occupational carcinoma.

Except for the color, the skin and hair appear normal. The vivid red discoloration fades on vitropressure and could be taken for a common port wine birth mark. It is made up of telangiectases, as in radium or x-ray

Fig. 18.—The milker's nodules, a rather rare stigma of farming: warty, umbilicated nodules, somewhat similar to molluscum contagiosum but of a peculiar deep red, as if painted with mercurochrome. They are supposedly due to the entrance of a cow's hair into the skin. Essentially a foreign body reaction.

dermatitis the result of the repeated vasodilating stimulation of the heat. It is a perfect example of erythema ab igne (fig. 6).

Suppose a body is burned beyond recognition or a living but speechless or amnesic person is unidentified.

A streak of a vivid birth mark-like red on a forearm will tell that the person's occupation was in a foundry or, in general, in a factory where he had to stand in front of a highly heated oven or boiler.

The junk collector shin is represented by abrasions, cuts, scars and pigmentation (fig. 7). In a minor degree

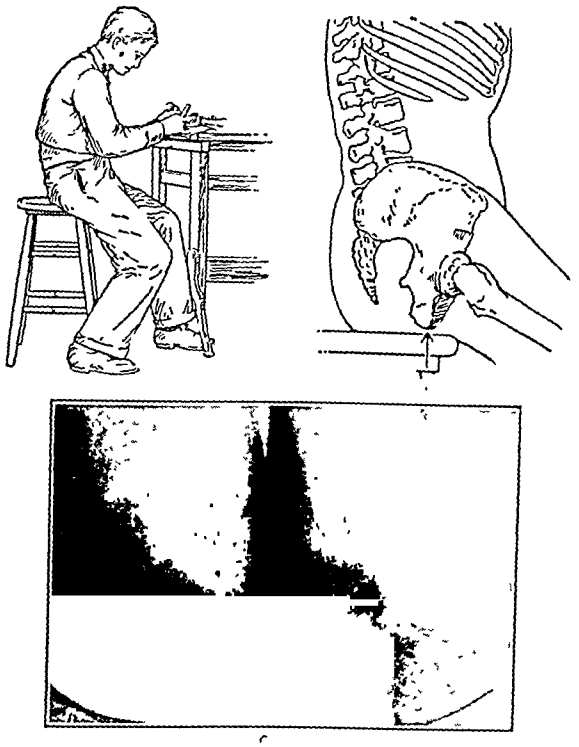

Fig. 19.—The marks of a sedentary occupation and their mechanism. Such an occupation is revealed by two areas of redness, scales, scars and atrophy due to the pressure on the skin between the seat and the ischium. Acne and boils may develop in this area from friction. An acneform dermatergosis like the one of the violin player. Two areas of hyperpigmentation may be found even if sedentary work has been discontinued for years.

the marks are noticeable in garbage collectors, truck drivers and foundry workers for the same reasons as the junk dealer and in railroad conductors, ship pilots,

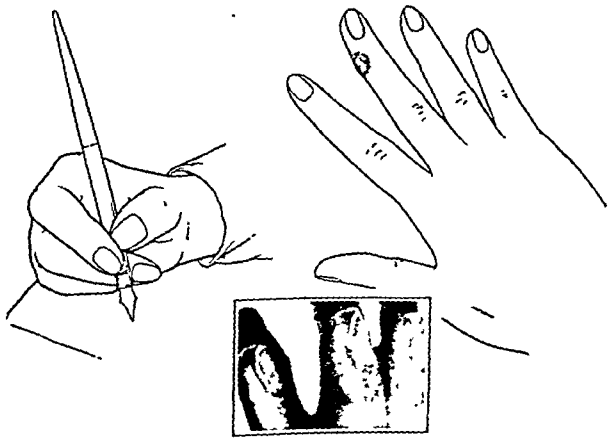

Fig. 20.—The writer's callus (of students, designers, bookkeepers), a stigma shared by dentists (from use of the drill), manipulators of small screw drivers (in work on jewelry, optical goods and precision instruments), painters from the brush and seamstresses from the thimble.

engineers and firemen, from hitting the steps of the railroad car or engine or ladder rungs.

Other interesting calluses are found in textile workers, bakers, shoemakers, tailors and cooks.

In the musical profession the callus on the neck of the violin or viola player is one of the most characteristic trade marks of all professions (fig. 8), a thick, acneform, scarry lump about the angle of the lower jaw, extending downward for a few square centimeters as a swollen area, soft, with hypertrophic hair follicles and sebaceous glands, with secondarily acne-like infected follicles, abscesses and finally acneform scars. Predisposition plays a great part in the development, size and severity of the violinist callus.

Characteristic calluses are found on certain finger tips of musicians, especially in the viola-violin, cello-contrabasso, guitar, saxophone, trombone, French horn (fig. 9) and jazz drum player (fig. 10).

The implements of some sports, such as the bar, the oar, the rope, the golf club, do not leave marks much different from what is produced by common manual labor, except for location; e. g., the golfer usually has calluses only on the left hand. The calluses of the golf player, shared by the baseball player, are also partly found in the carpenter. Characteristic calluses are found in the discus thrower, the bowler and the squash-tennis-badminton player. A characteristic mark is the permanently contracted in flexion tip of both little fingers due to the injury from passed balls in former baseball players.

But the best known of all are the cauliflower ears of the boxer (fig. 11). Most of the crushing is found

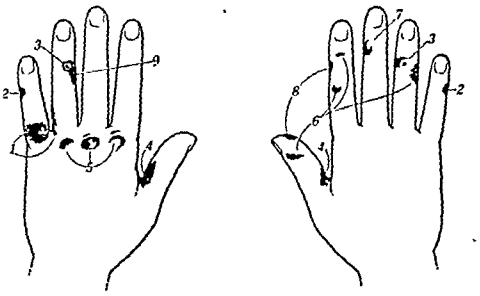

Fig. 21.—Ensemble of the most common calluses, cicatrices and stigmas: 1, the stone cutter's "ring"; 2, the burler; 3, the spectacle frame polisher; 4, the janitor-sweeper; 5, the landscape gardener; 6, the seamstress; 7, the writer, designer, dentist; 8, the barber; 9, the jazz band drum player.

on the left ear. With them go a flattened nose, a blind eye, scars on the eyebrows, dislocated thumbs and the build and sex of the body.

Scars, with few exceptions, are permanent, unremovable signs of something which has happened in the past. They stand as an unquestionable, unchallengeable proof of a past malady or operation or accident. Scars of the so-called Jericho or Aleppo boil or oriental sore (fig. 13), besides being a proof of previous disease, are a very valuable racial sign (Armenians).

Certain scars are positive signs of one disease or one operation, such as the scars of thyroidectomy, appendectomy, thoracoplasty, the square scar left by the radium plaque, the loss of substance of the frenum from a primary chancre, the typical archiform sequelae of late cutaneous syphilids, the radiating lines about the mouth remnants of infantile syphilitic rhagades and the scars of smallpox and of tinea favosa as a possible indication of foreign birth.

Dental lesions have been described in upholsterers, shoemakers and seamstresses from holding tacks or needles between their teeth. They seem to be of but small practical value.

Black-blue lines on the gums, cheeks or palate are valuable in demonstrating that the bearer is under bismuth therapy.

The only valuable professional or diagnostic sign obtained from the nails is left by trauma (saw bites, needle punctures, wheel or gear crushes, knife chopping, wear from handling rough material, chemical burns, infections, felons, x-rays and radium, wear and luster in severe chronic pruritus). However, the tiniest pit or detachment from the nail bed may be most valuable in the diagnosis of psoriasis.

Club nails, Beau's lines and spoon nails, in spite of hundreds of papers written and dozens of diseases or conditions held responsible for them, are interesting observations but of no diagnostic value.

SUMMARY

Stigmas and other body characteristics can be roughly divided in four groups according to their usefulness as an aid to personal identification:

1. Stigmas and characteristics very helpful because peculiar to one profession, one race, one disease or one operation. Such may be the calluses of certain musicians, the stone cutter, the sweeper, the barber, the shoemaker, the tailor, the cook; the telangiectases and burns of the foundry and optical glass molder; the scars of oriental sore, thyroidectomy, cocaine injection, radium and others; the odor from food or ashes; the color from various stains.

2. Stigmas and characteristics shared by more than one profession or disease or operation but helpful as an aid to personal identification. Such may be the calluses of the writer-designer-dentist, of the jeweler-engraver, of the mason (fig. 14) and file worker, of the plasterer-carpenter, of the gardener (fig. 15), plumber, housewife or textile worker, of the floor scrubber (figs. 16 and 17), plumber or praying kneeler; of the machinist, tool maker or knife, file or foundry worker; the scars

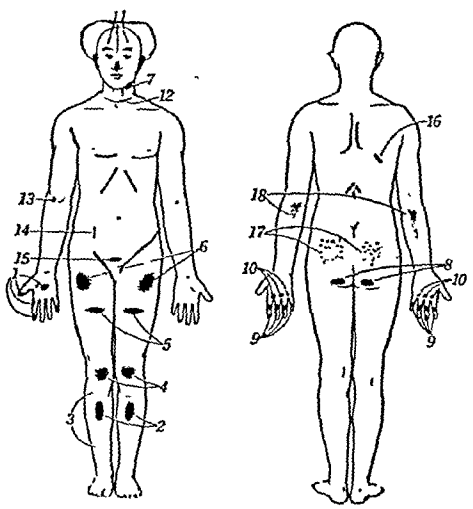

Fig. 22.—Ensemble, continued: 1, jewelers, engravers; 2, painters; 3, junk handlers, railroad workers; 4, floor scrapers, plumbers, those who kneel in prayer; 5, packers, bakers, leaning against table; 6, basket carriers; 7, violin, viola players; 8, marks of a sedentary occupation; 9, scrub women, plumbers, knuckle calluses; 10, landscape gardener (metacarpophalangeal knuckle calluses); 11, boxers', wrestlers', ears, nose, eyebrow scars; 12, thyroidectomy scar; 13, blood transfusion scar; 14, appendectomy scar; 15, steel brace mark; 16, empyema scar; 17, scar from old time antisyphilitic treatment; 18, packers or any workers leaning on the elbow.

shared by chickenpox and the remnants of removal of moles.

3. Stigmas and characteristics moderately helpful as an aid to personal identification. Such may be the packer-baker alopecia and acneform dermatergosis of the thighs from friction against the bench; the milker's nodules (fig. 18); the quite common marks on the buttocks in sedentary occupations (fig. 19); the nail mutilations in onychophagia as a sign of latent or well developed neurosis.

4. Stigmas and characteristics uncommon, rare or obsolete or from far away countries are interesting but of little value as an aid to personal identification. Such

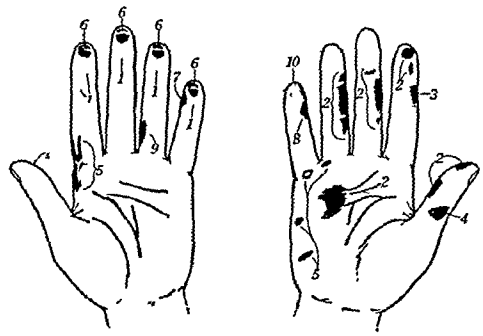

Fig. 23.—Ensemble, concluded: 1, masons' or bricklayers' worn out left finger tips; 2, jewelers, engravers; 3, barbers; 4, cobblers; 5, golf players; 6, stringed instrument players; 7, French horn players; 8, trumpet, tuba players; 9, trombone players.

may be the calluses of stevedores carrying coal baskets on their shoulders; the funnel shaped chest of the cobbler; the warty growths of cement, asbestos, fiberglass workers; the clean calluses of the soles in Turkish bath attendants.

CONCLUSION

Stigmas of a profession or disease are an interesting subject of study in dermatology and industrial medicine. In event of nonprintable fingerprints, which is not as rare as commonly believed, in amnesia and in other instances they may be a valuable addition to what is known in forensic medicine for personal identification.

170 Waterman Street, Providence 6.

ABSTRACT OF DISCUSSION

DR. LOUIS SCHWARTZ, Bethesda, Md.: The word "stigmas" is an unfortunate one to apply to abnormalities on the body resulting from occupation, because the word as usually used carries with it a connotation of infamy, while in dermatologic language it simply means the "brand of a trade" on the skin, and there is no intended derogation. The chapter "Die beruflichen Stigmata der Haut" by Dr. Moritz Oppenheim in the first volume of "Die Schädigungen der Haut" defines occupational stigmas of the skin as "the similar changes of the skin occurring in all persons engaged for a long time at a particular occupation." Many of the trade stigmas described in the European literature are not seen in the United States because of differences in the method of manufacture. Many of the old trade stigmas in the United States have disappeared because industrial progress has devised mechanical methods to replace manual operations. Trade stigmas may be classified as resulting from (1) physical forces such as heat, cold and radiation, (2) mechanical causes such as pressure and friction and (3) chemical causes. Some of the stigmas, such as callosities, are a result of an inflammatory response of the skin to irritation; however, they do not impair the worker's functional capacity but rather make it possible for him to continue work without inconvenience. This is a protective mechanism. Trade stigmas may also be classified as (1) transitory, such as callosities and nail changes, because they soon disappear after occupation ceases, (2) as long lasting, such as the comedones, acnes and melanoses, and (3) those which are permanent, such as argyria, keratoses and telangiectases.

DR. JOHN G. DOWNING, Boston: Stigmas must be recognized or they may be mistaken for nonoccupational entities;

for example, the tailor who dips his hands in water many times daily and smooths the cloth with his finger develops calluses which may become fissured, leaving a port of entry for secondary infection with a resulting disability. These might be mistaken for psoriasis, which is considered by most boards to be nonindustrial. I believe we shall see many stigmas resulting from oil folliculitis. These will consist of areas of atrophy, pigmentation and loss of hair, especially on the flexor aspect of the arms and the anterior surface of the thighs. While not disabling, they will be disfiguring. If the worker is a machinist, he will be prohibited from contacting cutting oils and therefore entitled to partial compensation. Undoubtedly many women will present claims as a result of these stigmas. The literature states that eruptions from external irritants or sensitizers are not sufficiently characteristic to incriminate the offending substances. However, to the trained observer certain exposures present definite physical signs. The average worker in a given trade gives a fairly consistent history of the site and character of the onset and presents an eruption which is reasonably characteristic of an occupational dermatosis. This has been my experience in cases from the shipbuilding industry with a dermatitis from zinc chromate, described by Hall occurring among aircraft workers (THE JOURNAL, May 20, 1944, p. 179). He even differentiates between patients suffering from a sensitivity to the zinc chromate alone from that due to the resin ingredient, segregating also those sensitive to both of the constituents in the primer. A tanner presents a hidelike appearance of the forearms. A shoe trimmer's dermatitis appears on the dorsum of the thumb, the radial aspect of the index finger and the dorsum of the hand over the right first and second metacarpals. The dry, fissured appearance of the tips of the right first, second and third fingers, with separation of the free border of the nails, suggests a treer's dermatitis, while the shoedresser discloses a dermatitis on the dorsum of the first, second, third and fourth fingers of the left hand, especially at the tips where he holds the sponge. A soda fountain clerk presents paronychias and vesicles on the lateral aspects of the fingers of both hands, with enlargement of the epitrochlear and axillary glands. A dishwasher's hands are edematous, with maceration of the interdigital spaces; a baker's hand has a similar appearance plus an eruption on the lower half of the ulnar area of the right forearm due to the rotary motion in kneading dough. The eruption of the chocolate dipper generally begins on the right fourth and fifth finger and the outer half of the dorsum of the right hand.

DR. MAURICE OPPENHEIM, Chicago: A few years ago a coal miner was accused of murdering his comrade in a coal mine. The defendant denied ever having worked in a coal mine, but an examination of his skin proved that he was a coal miner. This proof was brought about by the so-called coal line or coal stripe. By hammering the coal in the mines, splinters of coal perforate the skin regularly. These remain permanently. They are mostly in the face; they are on the hands and on other areas of the body too. They are black lines as found in munitions workers, not points as after explosions of gunpowder. These are permanent, because coal in the skin doesn't undergo any change. This coal line or coal stripe was found on the forehead of the accused man. So the conviction was there that he was a coal miner once, what he had denied. He was found guilty of murder. This is my classification of the stigmas of the skin: Transient stigmas: colorings, stratifications, rhagades and excoriations, nail changes, pigmentations and callosities. Permanent stigmas: cicatrices, telangiectasia, hypertrophy of connective tissue, bursa formations, permanent pigmentations, tattooings and impressions. The permanent stigmas are more important than the transient; the latter are limited in their values because during the time of unemployment the laborers are leaving their jobs and taking over other jobs; therefore they are lacking for identification. In the same way as we have experts at police headquarters for fingerprinting, we should have expert dermatologists there who know the stigmas, to help to establish identification of unknown people, and especially of criminals, which asks for a special study and training.

HEPATITIS FOLLOWING BLOOD OR PLASMA TRANSFUSIONS

OBSERVATIONS IN THIRTY-THREE CASES

CAPTAIN EMANUEL M. RAPPAPORT
MEDICAL CORPS, ARMY OF THE UNITED STATES

Hepatitis due to inoculation with homologous serum has received considerable prominence in medical literature during the past few years owing to its widespread incidence following inoculation of troops with normal human serum employed as a vehicle for the yellow fever virus. While the pathogenesis of this disease has not been definitely established, the result of considerable investigation in both this country and England suggests that the icterogenic agent is a virus which retains its virulence after storage for long periods in a dried state. Hepatitis has been produced experimentally in human volunteers by parenteral injection,[1] by feeding [2] and by nasal inoculation [3] of material containing the infective agent.

Similar sequelae following whole blood or plasma transfusions were reported in 9 cases by Morgan and Williamson [4] and in 5 cases by Steiner.[5] Beeson,[6] in describing the occurrence of jaundice in 7 cases following the use of pooled plasma and extracted whole blood, prophetically states that "the present large scale use of blood and plasma transfusions may lead to the occurrence of a considerable number of such cases of hepatitis."

Between May 1 and Dec. 31, 1944, 31 soldiers recently returned from overseas were referred to the gastrointestinal section of the Schick General Hospital because of jaundice which had developed in 9 while en route here and in 22 others while they were being treated in other sections at this hospital. All had previously received either blood or plasma transfusions, occasionally both, almost invariably necessitated by hemorrhage resulting from wounds in combat. Evidence will be presented which indicates that this complication resulted from transmission of the icterogenic agent via the medium of human blood products.

It is my chief purpose in this presentation to focus wider attention on this syndrome, with particular reference to the occasional development of subclinical or latent hepatitis, which is easily overlooked because of the absence of jaundice.

CLINICAL MATERIAL

This series comprises 33 patients, 31 of whom developed jaundice and 2 exhibiting latent hepatitis without visible jaundice. All were returned to this country following service in widely separated geographic areas, representing every theater in which our armies have been engaged in combat. Thirty-one had been originally admitted to the surgical service; 30 of these were battle casualties, while 1 had been subjected to a nephrectomy in Alaska because of carbuncle of the right kidney. Only 2 were referred from other sec-

tions of the medical service. Of the latter, 1 had been evacuated from the South Pacific area because of acute infectious eczematoid dermatitis and had received plasma to combat hypoproteinemia which resulted from oozing of serum from the skin lesions. The other was an evacuee from Australia with dementia precox who, while en route to the United States, developed pneumonia, multiple skin abscesses and secondary anemia. He had been given plasma on the hospital ship prior to admission to the West Coast hospital. Following an uneventful recovery he was transferred to the psychiatric section of this hospital, and jaundice developed five weeks after arrival here. In fact, the sudden onset of hepatitis always marred an otherwise satisfactory convalescence from a totally unrelated disease, usually of surgical nature.

Twenty-two patients developed jaundice one to six weeks following arrival at this hospital. In 9 others icterus had started either while en route to this country or shortly after reaching coastal hospitals. Six had been retained at the latter institutions for observation and transferred here when their condition permitted travel, while 3 were sent on to this hospital without preliminary study. Since the term "jaundice" in this discussion will be used relative to clinical icterus, the 2 cases of latent hepatitis will be accorded consideration apart from the others under the heading "hepatitis without jaundice."

It might be reasonably suggested that jaundice developing in some instances shortly after leaving overseas ports or even after arrival in this country could have been of the epidemic variety, since the disease is ubiquitous. That contact was not a factor in the epidemiology is based on the following considerations:

1. During the period covered by this survey, only those overseas evacuees who had previously received blood or plasma developed jaundice while in this hospital, as shown in the accompanying chart.

2. Battle casualties comprised less than 20 per cent of the total admissions here and yet constitute 93.8 per cent of the group in whom jaundice occurred.

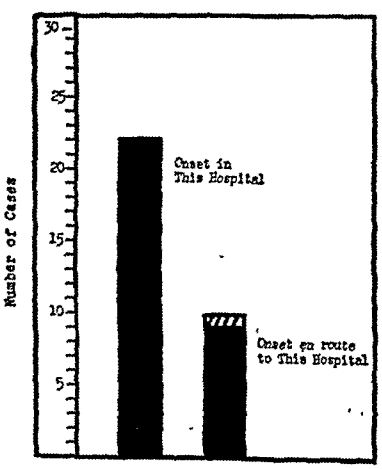
3. If hepatitis was of the epidemic or infectious type, it would be anticipated that chain spread would have involved other patients in the same wards, yet this did not occur in a single instance.

4. During the same period 32 patients observed at this hospital shortly after return from overseas duty acquired jaundice subsequent to leaving foreign ports; 31 had previously received transfusions. The lone exception was an evacuee who developed jaundice of undetermined origin the day he embarked on a hospital ship.

Thus the onset of this disease almost exclusively in those who had received blood products can hardly be considered either fortuitous or due to contagion.

INCIDENCE

It is impossible to determine accurately the frequency of this complication, as no statistics are available recording the number of soldiers who received transfusions prior to admission here. If it should be assumed that every combat casualty received blood or plasma, 2 to 3 per cent would form a conservative estimate of its incidence based solely on observations at this hospital. This estimate is subject to considerable variation and thus cannot be given wide application, since only the more seriously wounded require transfusions. Furthermore, as only the more complicated cases are evacuated and are more likely to have received multiple transfusions, the incidence of jaundice is probably higher among casualties returned to the zone of interior than those remaining overseas.



PREDISPOSING FACTORS

No specific factors predisposing to jaundice were noted other than the receipt of blood or plasma. The previous incidence of malaria, dysentery or other debilitating diseases, which are so commonly precursors of infectious hepatitis, was no more frequent in this group than in the nonjaundiced.

There was no antecedent history of alcoholism or liver disease in any of these patients. All had received penicillin and sulfonamide compounds several weeks prior to the onset of this disease.

VEHICLE AND LATENT PERIOD

Twenty-five patients had received 1 or more units of plasma. Four had been given plasma and blood, while, in 2, blood alone had served as the vehicle for the icterogenic agent. It was impossible to trace the original source of the tainted material, as available records merely indicated the amount employed, without denoting lot numbers.

Incidence of jaundice following evacuation from overseas. Solid columns, received blood or plasma; cross hatched, did not receive blood products.

The incubation period varied from nine to eighteen weeks, with an average of 12.6 weeks. Although multiple transfusions were given in 18 cases, the latent period was calculated from the date of the first injection, as no more than four days elapsed between the first and the last transfusion in any case. The long latency of the disease transmitted by inoculation as contrasted with the incubation period in epidemic hepatitis (approximately thirty days) has not as yet been explained. No relationship between the incubation period and the severity of the disease was noted.

SYMPTOMATOLOGY

Preicteric symptoms were frequently more disabling than those which attended the jaundice. Anorexia, malaise, lassitude, headache, chilly sensations, arthralgia, myalgia, epigastric pain and bloating, with nausea and occasional vomiting or diarrhea, were experienced by nearly all. These symptoms were so uniformly present before the onset of jaundice that in 2 cases the prediction that jaundice would follow was correctly made in the absence of positive physical findings. Fever up to 100 F. was present for one to three days in all cases observed in the initial stages. Prodromal symptoms lasted two to four days before jaundice became apparent and continued for three to five days thereafter but usually disappeard rapidly even before icterus began to recede. No correlation between intensity of jaundice and severity of symptoms was noted. Not a single patient in this series mentioned pruritus as a symptom unless specifically asked about itching. All reported

dark urine and pale stools before icterus became apparent. Abdominal pain was usually referred vaguely to the epigastrium or midabdomen, rarely to the right upper quadrant. None of those observed in the preicteric phase presented symptoms suggestive of biliary colic but rather of gastroenteritis or upper respiratory infection. Pain was never an outstanding symptom. Anorexia and lassitude were the complaints of longest duration, but the rapidity with which all symptoms disappeared despite intense icterus and pronounced hepatic dysfunction was remarkable.

CLINICAL FEATURES

This disease is clinically indistinguishable from infectious or catarrhal jaundice spontaneously acquired or from cases of yellow fever inoculation jaundice. The clinical features are so well known that it is unnecessary to dwell on them in detail. The most striking finding apart from the icterus was hepatomegaly without associated tenderness. Although hepatomegaly was noted in all cases, the degree of liver tenderness varied inversely with the extent of enlargement, contrary to expectations. Furthermore, the larger livers which extended 4 fingerbreadths below the costal border were extremely soft, pliable, nontender and with poorly defined lower border, whereas slight or moderate enlargement was usually characterized by firm consistency and an easily defined margin. With clinical improvement the liver receded, becoming firm and developing an easily palpable, tender border. The size of the liver was not directly related to the depth of icterus, nor did it invariably revert to normal size when jaundice had completely receded. Thus in case 5 in the table, with a maximum icterus index of 50, the liver extended to the pelvic brim, while in case 8, with an icterus index of 147, the lower edge never extended more than 1½ inches below the costal border. Occasionally the liver became progressively larger as jaundice diminished.

The incidence of splenomegaly was considerably less than is usually noted in infectious hepatitis. If splenic enlargement occurred it did not reach proportions rendering it palpable except in 1 of the 22 cases that were observed in this hospital from the onset of the disease (case 22). This is hardly a differential point. Abdominal tenderness, when present, was localized to the right of the midline in the midepigastrium, well above the liver edge.

At no time did any of these patients appear seriously ill, nor did their clinical appearance, apart from intense jaundice, reflect the laboratory evidence of severe hepatic involvement. Only 2 (cases 1 and 22) could have been considered moderately cholemic.

Bradycardia was uncommon, while transient urticaria appeared in only 2 cases. Tender axillary nodes developed in 4 cases. There was no correlation noted between age and severity of the disease.

LABORATORY FINDINGS

Blood Count.—Anemia, unless present prior to the onset of this disease, did not occur as a result of it. The white blood cell count, except in 1 case with wound sepsis, ranged between 5,200 and 6,850 with an average of 6,400 during the acute phase; polymorphonuclears varied between 39 and 60, lymphocytes between 36 and 56 per cent, with averages of 51 and 45 per cent respectively. Lymphocytes, particularly when associated with axillary adenopathy, necessitated the consideration of infectious mononucleosis, but serial heterophile antibody tests were uniformly negative. Platelets were normal or slightly diminished; reticulocytes, bleeding and coagulation time were normal.

Icterus.—The icterus index at its peak ranged from 50 to 185; in 10 cases it exceeded 100, while in 5 it never surpassed 75. The quantitative van den Bergh test (Malloy and Evelyn method) was invariably direct positive at the outset but became delayed in 4 during the recovery phase. No special significance is attached to it. The duration of visible jaundice was three and one-half to twelve weeks, with an average of four and one-half, but elevation of serum bilirubin was frequently demonstrated for long periods thereafter. As a rule the duration of hyperbilirubinemia was proportional to the initial intensity of jaundice.

Urine.—Albuminuria and cylindruria were noted in the very early phases in 3 cases. Bile was always demonstrated in the urine in the early stages but during the recovery phase was absent, despite obvious jaundice. Increase of urobilinogenuria as estimated quantitatively could be frequently demonstrated when serum bilirubin was slightly elevated or even normal and when other liver function studies were normal.

Stools.—Pallor of the stools appeared to antedate visible jaundice in most cases. Quantitative stercobilinogen studies were conducted when pale stools suggested acholia, but twenty-four hour specimens always contained more than 30 mg. of stercobilinogen, which is well above the level compatible with complete obstruction. If absolute biliary obstruction ever existed it was probably of short duration.

LIVER FUNCTION TESTS

All methods of evaluating liver function available at this hospital were applied from the earliest stage of observation. Serial studies at regular intervals afforded an effective means of determining the type and degree of hepatic involvement and permitted a reasonable correlation of the respective utility of the individual tests usually employed in assaying both severe and minimal liver damage. Where jaundice had antedated admission here, such complete studies were not initiated at previous installations, but their laboratory findings are incorporated with results obtained at this hospital. These are given in the table, which lists only pertinent data at selected intervals which clearly indicate the course of the disease in the individual case.

(*a*) *Hippuric Acid Excretion.*—The ability of the liver to synthesize hippuric acid was determined by estimating the four hour urinary excretion of hippuric acid after oral administration of 6 Gm. of sodium benzoate. Reduction in this function was evident in the early stages of the disease in all of the 22 cases tested. Rapid reversion to normal occurred in 17 even before jaundice disappeared, while low urinary levels persisted for prolonged periods in 5. In 2 patients without evidence of renal impairment but with severe liver damage, no hippuric acid was elaborated until the recovery phase (cases 16 and 22).

Results with the intravenous test devised by Quick[7] are not included in the table since the material was not available for use until the later phases of this study. Although more sensitive and remaining positive longer than the oral test, in the few cases of this series in

7. Quick, A. J.; Ottenstein, H. N., and Weltchek, H.: Synthesis of Hippuric Acid in Man Following Intravenous Injection of Sodium Benzoate, Proc. Soc. Exper. Biol. & Med. 38:77-78 (Feb.) 1938

which it was employed, normal results were occasionally obtained even in the presence of residual jaundice.

(*b*) *Galactose Tolerance* (40 Gm. oral method).—This test was employed in only 12 cases during the height of jaundice and was normal in 5. It is likely that the intravenous test would have proved more sensitive. Where abnormal results were obtained initially, return to normal occurred earlier than any of the other tests.

(*c*) *Cephalin-Cholesterol Flocculation* (Difco antigen).—The cephalin-cholesterol flocculation test of Hanger [8] was strongly positive at the peak of jaundice in 25 of the 31 cases in this series, dropping rapidly to normal usually within three to four weeks despite persistence of jaundice and other evidences of parenchymatous dysfunction. In 6 cases this test was negative or doubtfully positive throughout the disease despite definite hepatic damage.

(*d*) *Total Cholesterol-Cholesterol Esters.*—Total, free and cholesterol esters were determined by the Schoenheimer and Sperry method.[9] The maximum alteration of the total cholesterol-cholesterol ester ratio was almost invariably due to depression of the ester fraction during the acute stage This change was noted in 14 of 22 cases, some of which exhibited remarkably low levels. The total cholesterol showed no constant variation. Rise in the ester fraction paralleled clinical improvement but frequently lagged behind the galactose tolerance, cephalin flocculation and hippuric acid excretion tests in reverting to normal. It is to be emphasized that only serial studies are of any value in following the course of jaundice, owing to considerable variation in the total cholesterol and cholesterol ester levels obtained in normals.

(*e*) *Sulfobromophthalein Excretion* (5 mg. per kilogram, thirty minute test).—This test was used when serum bilirubin had returned to normal, as in the presence of an elevation of serum bilirubin above 2 mg. per hundred cubic centimeters retention of dye is inconclusive evidence of impaired function. It could thus be employed in only 18 cases in this series. Retention up to 5 per cent in thirty minutes, which is within normal limits, was present in only 4 patients. Complete clearance of dye was effected by 14 even though clinical evidence of persistent disease remained in some.

(*f*) *Plasma Proteins, Albumin/Globulin Ratio.*—Results of these determinations are not included in the table because plasma protein levels were difficult to evaluate in this series owing to the fact that many of these patients exhibited malnutrition even prior to the onset of jaundice, and their overseas records not infrequently indicated the existence of hypoproteinemia following hemorrhage and wound sepsis. Serial studies revealed no striking changes during the course of this disease, but there was a tendency toward diminution of the A/G ratio chiefly due to a rise in the globulin fraction. Hypoproteinemia, when noted at the onset of jaundice, was actively combated by the use of concentrated serum albumin, so that the albumin fraction occasionally rose despite progression of hepatic damage. Thus, three days after the onset of jaundice in case 22 plasma proteins were 5.7 Gm. per hundred cubic centimeters with A/G ratio of 0.88. Hypoproteinemia at this early stage of hepatitis could not be attributed to the recent liver insult but to previous sepsis which had resulted in considerable malnutrition. Despite evidence of severe disruption of normal hepatic function, plasma proteins rose to 7.0 with A/G ratio of 1.3 following daily parenteral injections of 25 Gm. of concentrated human serum albumin for six days.

(*g*) *Prothrombin Time.*—Significant prolongation of prothrombin time determined by Quick's [10] method was observed in only 1 case (case 22). An initial increase to 105 seconds (normal control 20 seconds) was restored to normal after fourteen days of intensive therapy. Similar changes of a much milder degree were noted in 3, but prothrombin time was normal in all others.

ANALYSIS OF RESULTS OF LIVER FUNCTION TESTS

As would be anticipated, maximum deviations from normal were present during the acute stage. Furthermore, a dissociation of different liver functions and capacities was demonstrated. While individual tests were normal in some cases, analysis of the results of the battery of procedures lends overwhelming support to the belief that disruption of liver function was primarily mediated by cellular damage. Confirming the observations of Turner and his co-workers,[11] impaired excretory function as evidenced by persistent hyperbilirubinemia appeared to dominate the later stages. However, since excretion of bilirubin is the normal function of the liver cell, this dysfunction may well reflect residual cellular damage rather than a faulty extracellular excretory mechanism. This survey further emphasizes the importance of employing a medley of diagnostic methods from the incipience of the disease, and the danger of leaning too heavily on individual or even multiple liver function tests in differentiating obstructive from hepatocellular jaundice. Thus, in cases admitted during the subacute phase, sole reliance on liver function tests would have indicated a subsiding extrahepatic jaundice. Serial studies, however, serve to reflect the remarkably rapid regenerative power of the liver.

MISCELLANEOUS DATA

Duodenal intubation for biliary drainage was instituted in 10 cases to recover bile for microscopic study and not for therapeutic purposes. This procedure was undertaken during the period when jaundice was intense. Bile was obtained in all cases subjected to this procedure and presented a normal macroscopic appearance except that it appeared less concentrated, and B bile could not be identified. Microscopic studies were not remarkable. Occasional pus cells were found in 6 and tyrosine crystals in 1 (case 3). Cholesterol crystals were observed in 4 specimens, probably resulting from diminished bile salts causing precipitation of crystals. Cholecystograms with a double dose of oral dye were taken in 10 cases following subsidence of visible jaundice, because of persistent fat intolerance, of tenderness in the right upper quadrant or of the previous demonstration of cholesterol crystals in the bile. The gallbladder was visualized in all cases and

displayed adequate contraction with fatty stimulation and contained no calculi. Gastric analysis and gastroscopy in cases with persistent dyspepsia were normal.

COURSE

As a rule, jaundice reached its peak of intensity in seven to twelve days after onset of symptoms and then subsided gradually. Sixteen patients were still under observation three to five months after the onset of the disease and some showed symptomatic clinical or laboratory evidence or combinations of these criteria, which, if not conclusively indicative of residual hepatitis, suggested functional or morphologic alterations in the liver.

Abnormal clinical findings alone were unquestionably the most frequent residuums. Tenderness along the right costal border, with or without a palpable liver, was almost invariably found long after complete subsidence of jaundice. When palpable, the liver was firm and tender even when, with considerable enlargement in the early stage, tenderness to pressure had not been noted. Intolerance of fatty foods and pain in the right upper quadrant on bending were the commonest residual symptoms. Slight hyperbilirubinemia or increase in urinary urobilinogen with otherwise normal liver function tests were occasionally the only laboratory findings indicating persistent hepatitis.

HEPATITIS WITHOUT JAUNDICE

The possibility that subclinical forms of hepatitis may result from causes similar to those evoking frank jaundice is well known. Such cases are easily overlooked in soldiers who have sustained multiple wounds, particularly abdominal, because mild, transient symptoms such as anorexia, nausea and lassitude in the absence of visible jaundice may be considered secondary to their primary disease.

This syndrome is illustrated by the following cases:

A.—A private aged 20 sustained shell fragment wounds of his left ankle Sept. 15, 1944. He was given a 250 cc. plasma transfusion the same day, fragments were removed and a cast was applied Recovery was uneventful and he was evacuated to the United States, arriving at this hospital November 14. He

Summary of Cases

* Cases 1 to 22 observed from onset of disease; cases 23 to 31 transferred from other hospitals.
† Normal, 2.5-3.3 Gm. in 4 hours.
‡ Normal, 3.0 Gm. or less in 5 hours.
§ Normal, up to 5% in 30 minutes.

was 1 of 20 patients who, having received plasma three to five months previously, were selected at random in an orthopedic ward for determination of the icterus index and quantitative van den Bergh on December 29 with a view to uncovering cases of latent jaundice. His icterus index was 9.1 and van den Bergh 1.3 mg. per hundred cubic centimeters delayed. Results in all the others of the group were normal. Questioning revealed that for the past two weeks he had noted lassitude, anorexia, nausea and epigastric bloating, although he had not reported his symptoms to the ward officer. Examination revealed no visible icterus. The only significant finding was a firm, tender liver palpable 2 fingerbreadths below the costal border. The spleen was not enlarged. Hemoglobin was 13.5 Gm., the red blood cell count 4,750,000 and the white blood cell count 5,300, with 49 per cent polymorphonuclears and 51 per cent lymphocytes. A comprehensive laboratory survey was instituted, including cholecystogram, x-ray examination of the upper gastrointestinal tract, gastric analysis and gastroscopy, all of which were normal. Cephalin flocculation, hippuric acid excretion (oral and intravenous), urinalysis, heterophile and sedimentation index were normal. Sulfobromophthalein retention in forty-five minutes (5 mg. per kilogram) was 36 per cent.

On Jan. 10, 1945 the icterus index was 9.5 and serum bilirubin 1.5 mg. per hundred cubic centimeters. Because of continuation of his symptoms, he was placed on a low fat, high carbohydrate and protein diet. Symptomatic response was almost immediate.

On January 23 he was relatively asymptomatic on the foregoing regimen and the liver was barely palpable but still tender. The icterus index was 9.0 and serum bilirubin 1.1 mg. per hundred cubic centimeters. Sulfobromophthalein retention in forty-five minutes was 32 per cent. On February 26 the following results were obtained: serum bilirubin direct, 0.35 mg. per hundred cubic centimeters, indirect 0.30 mg. per hundred cubic centimeters (normal); total cholesterol 148 and cholesterol esters 59 mg. per hundred cubic centimeters; cephalin flocculation +; sulfobromophthalein retention 22 per cent in forty-five minutes; hippuric acid excretion after intravenous injection

of 1.77 Gm. of sodium benzoate 0.4 Gm. (normal 0.7-0.9 Gm.); 2 to 4 p. m. urine urobilinogen 1.05 mg. (normal). Although he felt well, the liver was still palpable and slightly tender. This patient is still under observation.

B.—A sergeant aged 25, with three years of military service during which time he had never noted dyspepsia, on Sept. 1, 1944 sustained shell fragment wounds of his right arm with a compound fracture of the right humerus. Following débridement a cast was applied and 500 cc. of plasma was administered. Convalescence was satisfactory and he was eventually admitted to this hospital November 28. He was referred to the gastrointestinal section for consultation on December 29 because of nausea, anorexia and upper abdominal distress of one month's duration. The only significant finding was a decidedly tender liver the firm lower edge of which was palpable 2 fingerbreadths below the costal border. The spleen could not be felt. Repeated determinations revealed that serum bilirubin ranged between 1.0 and 1.3 mg. per hundred cubic centimeters and urinary urobilinogen was elevated. Cephalin flocculation and hippuric acid excretion (oral and intravenous tests) were normal. Complete investigation of the gastrointestinal tract, including a cholecystogram, proved normal. He was given a diet high in carbohydrates and proteins with limitation of fat and showed rapid symptomatic improvement, although after three weeks the liver was still tender but barely palpable.

Too much reliance must not be placed on liver function tests in the diagnosis of mild hepatitis of short duration. It has been amply demonstrated that even in cases with jaundice the clinical features of subacute hepatitis were not directly or precisely correlated with the laboratory findings.

MANAGEMENT

Whenever possible patients were transferred to the gastrointestinal section for observation and treatment until at least clinical jaundice had subsided. No supplementary vitamin therapy was prescribed, sole reliance for nutritive requirements being placed on adequate carbohydrate and protein intake. Of late a modified Varco diet has been employed to advantage, using gastric intubation if indicated. In combating hypoproteinemia, however, concentrated serum albumin has given gratifying results unattended by any reactions noted with plasma or blood. Intravenous glucose and saline solution were rarely indicated. Surgical procedures were delayed until jaundice had receded and normal liver function had recovered in large measure. Jaundice per se was not considered an indication for absolute bed rest, and all patients were encouraged to partake of mild activity as the disease showed signs of subsiding. Convalescence appeared to proceed as rapidly in the ambulatory group as in those confined to bed because of casts or traction appliances.

COMMENT

Since blood products are administered as an emergency and frequently life saving measure, it is fortunate that the sequelae herein reported have thus far been unattended by any deaths despite the extreme initial cellular damage produced in the liver.

Pooling of plasma probably increases considerably the incidence of jaundice among the recipients. However, this procedure has been recommended to diminish the titers of isoagglutinins mainly by dilution and to some extent by action of group substances in neutralizing isoagglutinins, thus permitting universal use of plasma regardless of blood grouping. Hence the method employed to avoid initial severe post-transfusion reactions serves to increase the incidence of delayed jaundice. It is believed that the latter is the less objectionable, since severe reactions coming at a time when the recipient is in a precarious state might prejudice his chances of survival and interfere with urgent surgical procedures. An alternative to pooling would be the addition of purified solutions of group substances to plasma as suggested by Witebsky.[12] The use of plasma of the same group as the patient is obviously impossible in battlefield emergencies. Unfortunately skin tests to determine the sensitivity of the recipient to the icterogenic serum have been unsuccessful. While it has been demonstrated that ultraviolet radiation renders this agent innocuous, this seems unpractical for use on a large scale.

The most promising approach to the problem is the recent success attained by Stokes and Neefe[13] in preventing and attenuating infectious hepatitis by intramuscular injection of gamma globulin in subjects exposed to the disease. As most effective results were obtained by early injection, addition of gamma globulin to pooled plasma prior to its use or administering it early in the incubation period of jaundice to all individuals who have received plasma warrants trial as a prophylactic measure.

Oliphant[1] found that the jaundice producing agent is present in the blood during the preicteric stage but not after two and one-half months following disappearance of jaundice, and somewhat similar findings were obtained by MacCallum and Bauer.[14] This indicates that blood donors who constitute the greatest menace are those in the preicteric stage, or with hepatitis unattended by jaundice, as obviously individuals who have recently recovered from jaundice are not accepted at Red Cross blood banks. In view of the widespread incidence of infectious hepatitis, a transient "healthy carrier" state might exist among some volunteer blood donors and detection of such depositors would be impossible.

It has been repeatedly stressed that prevention would be aided by recording the lot number of each flask of plasma at the time of its use, thus permitting ultimate withdawal of contaminated batches. This method was found practicable with yellow fever and measles vaccine and may be applied to blood and plasma as employed in civilian hospitals. The problem presented by this discussion is more complex, since multiple transfusions are frequently given within a few days in the course of evacuation from first aid stations to the rear, and, in view of the wide variation of the incubation period, it would be extremely difficult to incriminate any one lot. However, valuable information could be obtained from records of patients receiving but a single transfusion, as even if the entire lot of plasma had been exhausted when it fell under suspicion the source of contamination might be traced.

Observations here suggest that quantitative bilirubin determinations be performed routinely on all patients who have received plasma or blood from doubtful sources at monthly intervals from the third to the sixth month after transfusion. This procedure is considered to be of more than academic interest since hepatitis "sine ictero" might result in sequelae as disabling as hepatitis

with jaundice. Unless the etiology is established at the outset, its recognition at a later stage may be extremely difficult.

While this series represents the largest reported to date of hepatitis resulting from the therapeutic use of blood or plasma, it is likely that this syndrome will be encountered and recognized more frequently in the future. Many cases which belong in this category have hitherto been erroneously considered infectious hepatitis. On the other hand, rigid criteria for diagnosis of homologous serum jaundice should be established lest the onset of hepatitis in all battle casualties be considered related to blood products received following shock and hemorrhage. Nevertheless with mounting casualties necessitating the use of pooled plasma on an ever increasing scale, it is likely that, with the exception of epidemic hepatitis, transfusions may constitute the largest single cause of acute hepatitis with jaundice until a method is devised for either detecting donors harboring the agent or for rendering the latter innocuous by treating the plasma prior to use.

SUMMARY

1. Thirty-two patients evacuated from overseas developed jaundice either en route to or following admission to an inland general hospital. All had received plasma or blood transfusions nine to eighteen weeks previously.

2. Evidence strongly suggests that the parenteral blood products acted as a vehicle for the icterogenic agent.

3. Serial laboratory studies corroborated the clinical impression that the resultant hepatitis was primarily parenchymatous.

4. Despite hepatomegaly, intense icterus and almost uniform laboratory evidence of derangement of the liver function, the clinical picture did not reflect the severe hepatic damage in the acute phase.

5. Subclinical hepatitis resulting from homologous serum may pass completely unrecognized because of absence of jaundice.

6. Quantitative van den Bergh estimation should be determined at monthly intervals from the third to the sixth month following receipt of pooled plasma as a simple method of uncovering latent hepatitis.

7. Since persons with a history of recent jaundice are not accepted as volunteer donors at blood banks, it is suggested that the icterogenic agent may be transmitted by subjects in the preicteric phase of infectious hepatitis or by "healthy carriers."

8. Because of multiple transfusions administered at successive medical installations in the course of evacuation, the problem of tracing the contaminated plasma responsible for this complication is extremely complex. Nevertheless, valuable information might be obtained in tracing the source of contamination if plasma lot numbers were recorded immediately following use.

9. The prophylactic use of gamma globulin either by addition to pooled plasma or by intramuscular injection subsequent to transfusion appears to warrant trial.

10. Apart from epidemic hepatitis, transfusions may constitute the commonest cause of jaundice occurring in the armed forces at present

THE HYPEREMIA EFFECT OF GONADOTROPINS ON THE OVARY

AND ITS USE IN A RAPID PREGNANCY TEST

BERNHARD ZONDEK, M.D.
FELIX SULMAN
AND
RIVKA BLACK
JERUSALEM, PALESTINE

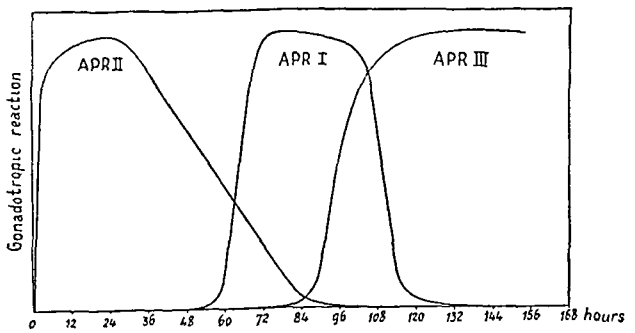
The hormone pregnancy test is based on the following facts:

1. The gonadotropic reactions of the ovary in infantile rodents:[1] anterior pituitary reaction I, follicle ripening and induction of vaginal estrus; anterior pituitary reaction II, hyperemization of the ovary and follicle hemorrhage (blood dots); anterior pituitary reaction III, formation of corpora lutea.

2. The production and excretion in large amounts of gonadotropic hormone in pregnant women, monkeys and equines (but not in other mammals).[2] Immediately after nidation of the egg in the endometrium, production of the gonadotropic hormones occurs explosively in such great quantities that even small amounts of blood or urine suffice to induce the aforementioned gonadotropic reactions. The hormone appears in lower concentrations in the blood than in the urine.

APPLICATION OF THE ORDINARY HORMONE PREGNANCY TEST AND ITS MODIFICATIONS

The ordinary hormone pregnancy test and its modifications are carried out most dependably on the ovaries of infantile rodents. The three gonadotropic reactions are induced by two different factors: the follicle stimulating hormone yielding anterior pituitary reaction I, and the luteinizing hormone yielding anterior pituitary reactions II and III. In developing the pregnancy test it was found that only anterior pituitary reactions II and III may be used for an accurate evaluation of the test; viz., only the presence of large amounts of the luteinizing hormone indicates pregnancy. Increased quantities of the follicle stimulating hormone may be excreted in the urine in conditions other than pregnancy (polyhormonal amenorrhea, climax, tumor); hence an error of about 10 per cent would arise through the application of anterior pituitary reaction I for the diagnosis of pregnancy, thus upsetting the practical value of the reaction. The anterior pituitary reaction I, as will be shown later, is however of diagnostic importance in certain cases of disturbed pregnancy.



As we shall see, not all infantile rodents react in the same manner to chorionic gonadotropin. A most striking reaction, easily distinguished with the naked eye, is the induction of the blood dot which protrudes from the ovary. Infantile mice were chosen for the original hormone pregnancy test because of the ease with which blood dots are found in this species. The test animals are injected subcutaneously over a forty-eight hour period with 1.8 to 2.4 cc. of urine (six injections of 0.3 or 0.4 cc.) and are opened for inspection ninety-six hours later. The test thus takes four days. This delay is undoubtedly a shortcoming of the method.

MODIFICATIONS OF THE ORDINARY HORMONE PREGNANCY TEST

Repeated attempts have been made to shorten the duration of the reaction. In 1930 the senior author [3] described a rapid pregnancy test in which precipitation of the gonadotropin from pregnancy urine with alcohol was employed. The precipitate was washed with ether and later dissolved in water. This method affords the injection of larger quantities of hormones (the equivalent of up to 14 cc. of urine in every mouse) and the result could be ascertained in fifty hours. This method was further studied and recommended by Eberson and Silverberg [4] and by Latzka.[5] The disadvantage of this rapid method is that the precipitation of the hormone takes several hours and complicates the procedure. Furthermore, the precision of the method does not approximate that of the original hormone pregnancy test.

An important contribution was the modification proposed by Friedman,[6] in which the urine is injected intravenously into rabbits instead of subcutaneously into mice. This reaction can be read in thirty-six to forty-eight hours later from the blood dots of the ovary. Hence, in this method too the anterior pituitary reaction II serves as the basis of the test. The shortcoming of this modification lies in the fact that the rabbits

Time relationship of reactions: APR II (hyperemia of ovary), APR I (estrus) and APR III (formation of corpora lutea).

have to be kept in separate cages for four weeks before beginning the test, so as to obviate any attempts at mating, which may cause ovulation and so falsify the reaction. Good results have also been obtained with infantile rabbits, but this requires well organized breeding, as only animals weighing more than 800 Gm. give reliable reactions. We have found that in the subtropical climate of Palestine the rabbit test may be faulty. This is especially true in the spring and summer months during spells of sirocco (hamsin), as this hot dry wind may cause spontaneous formation of follicle hemorrhages (anterior pituitary reaction II).

THE HYPEREMIA EFFECT OF CHORIONIC GONADOTROPIN AS A PREGNANCY TEST

Zondek and Aschheim [7] showed that in infantile rodents strong hyperemia of the ovary and follicle hemorrhages (anterior pituitary reaction II) may be evoked by the implantation of pituitary anterior lobe or placenta and by the injection of blood or urine from pregnant women. This is accompanied by anterior pituitary reaction I, which evokes vaginal estrus (cornification) and luteinization of the ovary (anterior pituitary reaction III). It is interesting to note that the ovaries of different species of rodents react differently toward the administration of gonadotropic hormone.

In the infantile mouse the ovary is normally somewhat hyperemic; this hyperemia is enhanced by gonadotropic hormone, and the formation of blood dots is brought about. The infantile rat reacts otherwise. In this animal the ovary is anemic and gonadotropins scarcely provoke blood dot formation, but at an early stage extreme hyperemia of the whole ovary takes place, so that it stands out in a most characteristic way from the pale tubes and the uterus. In the infantile rabbit the ovary is also anemic but, in contrast to the rat, blood dots appear regularly, whereas the hyperemia reaction of the whole ovary is absent. Common to the three rodents is the stimulation by gonadotropin resulting in formation of corpora lutea (anterior pituitary reaction III). Hence the blood dot (anterior pituitary reaction II) is not a necessary feature of the gonadotropin reaction. If the blood dot is to be used as the indicator for gonadotropin, the mouse or rabbit is the most suitable test object, whereas if hyperemia is to be used the rat is most fitting.

TIME FACTOR

The gonadotropic reactions of the ovary (anterior pituitary reactions I-III) appear at different time intervals in the rat. Estrus appears between the sixtieth and the eightieth hour and corpus luteum formation between the eighty-sixth and the one hundred and twelfth hour. The hyperemia of the ovary is the first reaction, beginning in two hours (with pituitary gonadotropin even in fifteen minutes and with pregnant mare blood gonadotropin after three to four hours); it has its peak at the twenty-fourth hour and disappears within thirty-six to forty-eight hours, as shown in the accompanying chart. Thus it is obvious that the minimum period for hyperemia to set in is very short.

RELATION BETWEEN HYPEREMIA UNIT, ESTRUS UNIT AND CORPUS LUTEUM UNIT

We have designated as 1 hyperemia unit that amount of gonadotropic hormone which induces hyperemia of the whole ovary in an infantile female rat within twenty-four hours. We have investigated the quantitative relations of the hyperemia unit, the estrus unit and the corpus luteum unit in the rat with a single injection and the reactions were read as follows: for the hyperemia unit, twenty-four hours later, for the estrus unit in ninety-six hours and for the corpus luteum unit in one hundred and twenty hours. We also determined these values for three gonadotropins: (*a*) chorionic gonadotropin from pregnancy urine, (*b*) pregnant mare blood gonadotropin and (*c*) pituitary gonadotropin (sheep hypophysis). We shall here give only a summary of these examinations as carried out on 3,000 infantile female rats.

A puzzling fact was encountered in that the hyperemia unit varies considerably with different gonadotropins. The most active was pituitary gonadotropin, which evokes hyperemia with one tenth to one twentieth of the quantity of hormone necessary to induce vaginal estrus or luteinization. The most ineffective is pregnant mare blood gonadotropin, of which ten times the amount of hormone is needed for hyperemization as for estrus. With chorionic gonadotropin from pregnancy urine, the quantity of hormone needed for the hyperemia effect is intermediate: hyperemia is brought

on with the same amount which evokes estrus, whereas for luteinization three times the amount is necessary.

What conclusions may be drawn from these facts? It is possible that the hyperemia factor, whose effect is rapid and limited to a certain time interval (one-fourth to forty-eight hours), is a special factor, viz. a third hormone. This question can be decided only with experiments on hypophysectomized animals, which we intend to carry out. It is also possible that hyperemia is evoked by optimal proportions of follicle stimulating hormone and luteinizing hormone in the injected preparation. Chorionic gonadotropin contains preponderantly luteinizing hormone and pregnant mare blood gonadotropin chiefly follicle stimulating hormone, whereas pituitary gonadotropin contains follicle stimulating hormone and luteinizing hormone. Hence pituitary gonadotropin can evoke anterior pituitary reaction II with a minimum dosage in a minimum of time. On the other hand, pregnant mare blood gonadotropin containing follicle stimulating hormone and chorionic gonadotropin containing only luteinizing hormone must be given in larger doses.

It seems that hyperemia is evoked mainly by luteinizing hormone and that follicle stimulating hormone has only an augmentative effect. This would be in agreement with the conception of Zondek (1931-1935)[8] that the follicle hemorrhage, which constitutes the peak reaction of hyperemia, arises from a combined effect of follicle stimulating hormone and luteinizing hormone. The important fact which emerges from this discussion is that with pregnancy urine gonadotropin the hyperemia hormone pregnancy test is evoked with one third the amount of hormone that is necessary for luteinization. This renders the hyperemia hormone pregnancy test especially sensitive for the diagnosis of pregnancy.

RESULTS WITH THE HYPEREMIA HORMONE PREGNANCY TEST

There have been repeated attempts to use the hyperemia effect of chorionic gonadotropin as a pregnancy test. The first experiments were reported by Reiprich[9] and by Zondek.[10] Reiprich[9] injected infantile rats with quantities of urine as large as 10 to 14 cc. and found a positive reaction in twenty-four to thirty hours. Zondek[10] observed that such large amounts of urine are apt to give false results, especially in cases in which the follicle stimulating hormone content of the urine is high (menopause and tumors). The hyperemia reaction was further studied and employed for the diagnosis of pregnancy by the Walkers[11] and Falls, Kelso,[12] Frank and Berman,[13] the Salmons, Geist, Frank and Poole,[14] Kupperman and his associates,[15] Kaminester,[16] Kline[17] and Farris.[18]

For an exact diagnosis of pregnancy, special emphasis should be laid on the right dose, since the injection of excessive amounts of urine results in positive reactions from nonpregnant women with functional disturbances involving increased excretion of follicle stimulating hormone. When, for example, we injected 10 cc. of pregnancy urine, as proposed by Frank and Berman,[13] we obtained false positives, from which we concluded that the dose was too high. Generally, 20,000 rat units (estrus units) of gonadotropin is excreted in 1 liter of the urine of early pregnancy, so that 1 cc. contains 20 estrus units. The excretion of luteinizing hormone is about 5,000 to 10,000 rat units per liter. Since the estrus unit equals the hyperemia unit, it is obvious that 1 cc. contains 20 hyperemia units. We have found the most practical dose to be 4 cc. of pregnancy urine. This is given to the infantile female rat in two injections of 2 cc. each at an interval of one hour. The site of injection is the subcutis of the neck.

* A case of myoma; the ordinary hormone pregnancy test was negative in all 5 mice injected, but prolan A was positive. In the 24 hour hyperemia test 1 of the 3 rats employed reacted positively. The 2 and 6 hour test was negative.

† A case of corpus luteum persistens. The patient had a negative ordinary hormone pregnancy test, but the urine contained 500 M. U. prolan A and 250 M. U. prolan B. The latter finding could not be revealed by the ordinary hormone pregnancy test since it only indicates the presence of more than 417 M. U. prolan B. The hyperemia test was negative after 2 and 6 hours, but positive in all 3 rats used for the 24 hour test.

Up to now we have tested 300 cases. In 200 cases (table 1) the previous diagnosis was unknown and the results were vertified by the ordinary hormone pregnancy test carried out on infantile mice. In a further 100 cases (table 2) the urine samples were taken from patients in our department. In these cases the diagnoses from the clinical data were known to the senior author but not to the laboratory personnel. The cases studied, which are compiled in tables 1 and 2, include early pregnancy, late pregnancy, extrauterine pregnancy, abortion, benign and malignant tumors, the menopause, polyhormonal disturbances, primary and secondary amenorrhea, febrile infections and normal subjects. Patients with tumors were tested only when the type of the tumor could be verified by laparatomy (Z.). In order to ascertain the time interval at which the hyperemia reaction gives most exact results, the animals were killed two, six and from eighteen to

* A case of pseudomyxoma ovarii. The hyperemia test was negative after two and six hours, but 1 of the 3 rats used for the twenty-four hour test reacted positively.

twenty-four hours after injection. The results in our 300 cases (tables 1 and 2) were as follows:

1. *Two Hour Test.*—Of 98 cases of early pregnancy (one to three months) 33 false results were obtained in which pregnancy was not diagnosed. Of 30 cases of late pregnancy (four to nine months) we obtained 7 false results. In all, there were thus 40 mistakes in 128 pregnancies, a 31.2 per cent error. It must, however, be emphasized that whenever the two hour test was positive the result was correct. In other words, the two hour test can be used only if the result is positive, whereas negative results cannot be evaluated. Positive reactions were never obtained with the urine of nonpregnant women, which is obvious since the test is uncertain even in the presence of great amounts of chorionic gonadotropin in pregnancy. In the whole series of 300 cases tested, which comprised patients in various conditions, we had 45 false results, i. e. a 15 per cent error.

2. *Six Hour Test.*—The results with the six hour test were much better. Here we had 11 false results out of 300 cases, i. e. an error of 3.7 per cent. Unfortunately, the source of error is much greater if only the cases of pregnancy are considered. Here we found 6 false results in 98 cases of early pregnancy, and 3 mistakes in 30 cases of late pregnancy. This gives 9 erroneous results in 128 cases of pregnancy, an error of 7.8 per cent. The six hour test is very reliable if it is positive but is inconclusive when negative. We are now going to improve its reliability.

3. *Twenty-Four Hour Test.*—There was a very great improvement with the twenty-four hour test. In 98 cases of early pregnancy and 30 cases of late pregnancy all the tests proved correct. This would mean a precision of 100 per cent. On the other hand, we had 3 false results with nonpregnant patients. These were (*a*) a case of myoma, (*b*) a case of pseudomyxoma ovarii and (*c*) a case of corpus luteum persistens. It is known that in such cases even the ordinary hormone pregnancy test may be positive. Hence in 300 cases we had 3 false positive results, an error of 1 per cent.

For clinical purposes it is usually quite sufficient to have a precise result within twenty-four hours. It is only rarely that the result is required urgently on the same day. In these cases the six hour test and even the two hour test may be tried. In such cases it should be made clear that the two and six hour tests can be used only if they are positive. If they are negative, pregnancy cannot be excluded and the correct answer can be given only within twenty-four hours.

Technic.—Our routine technic is as follows: We use 3 infantile female rats, 3 to 5 weeks old, weighing 20 to 25 Gm., for every examination. They receive 4 cc. of urine each in two injections of 2 cc. at an interval of one hour. Injections are given subcutaneously into the neck. One rat is killed after six hours and the other two are killed in twenty-four hours. The reaction is positive if hyperemia appears in at least one ovary of 2 different rats. As a rule all ovaries react similarly. The rats are killed with ether, chloroform or illuminating gas, opened and the uterine cornua lifted with a forceps. The ovaries are often covered with fat. In this case they should be turned and the fat is carefully teased away, any lesion being avoided which may cause hemorrhage. The ovaries may be inspected in bright daylight, in direct sunlight or by electric light. Comparison should be made with the color of the spleen or kidney. If the reaction is positive the ovaries are slightly brighter than these organs, nearly strawberry red. The hyperemia should extend to the whole ovary and not only to single follicles. The operator should be able to distinguish red clearly.

HYDATIDIFORM MOLE AND CHORIONEPITHELIOMA

The ordinary hormone pregnancy test has obtained special significance in the diagnosis of pathologic pregnancy. Following the demonstration that in hydatidiform mole excretion of gonadotropic hormone is greatly increased,[19] the quantitative determination of chorionic gonadotropin in the urine has become of special importance for differential diagnosis of hydatidiform mole and chorionepithelioma. There are even certain types of malignant tumors of the testis which may be diagnosed by means of the urine.[20] This was the first demonstration of diagnosis of malignant tumors through the urine, and it has even been possible to determine by this means the type of tissue from which the tumor originated.

In 2 cases of hydatidiform mole and 1 of chorionepithelioma we compared the hyperemia hormone pregnancy test in the rat with the ordinary hormone

20. Zondek, B.: Chirurg **2**: 1072, 1930; Klin. Wchnschr. **11**: 274, 1932.

pregnancy test in the mouse. The urine was given in diluted form.[21]

CASE 1.—*Hydatidiform mole.* The ordinary hormone pregnancy test showed follicle ripening and induction of vaginal estrus (anterior pituitary reaction I), 1,000,000 mouse units per liter of urine; hyperemization of the ovary and follicle hemorrhage, with formation of corpora lutea (anterior pituitary reactions II and III), 500,000 mouse units. The hyperemia hormone pregnancy test showed ovarian hyperemia (anterior pituitary reaction II), 500,000 rat units.

CASE 2.—*Hydatidiform mole.* The ordinary hormone pregnancy test showed follicle ripening and induction of vaginal estrus (anterior pituitary reaction I), 200,000 mouse units per liter of urine; hyperemization of the ovary and follicle hemorrhage, with formation of corpora lutea (anterior pituitary reaction II and III), 100,000 mouse units. The hyperemia hormone pregnancy test showed anterior pituitary reaction II, 200,000 rat units.

CASE 3.—*Chorionepithelioma.* The ordinary hormone pregnancy test showed follicle ripening and induction of vaginal estrus (anterior pituitary reaction I), 6,000,000 mouse units per liter of urine; hyperemization of the ovary and follicle hemorrhage, with formation of corpora lutea (anterior pituitary reactions II and III), 3,000,000 mouse units. The hyperemia hormone pregnancy test showed anterior pituitary reaction II, 3,000,000 rat units per liter of urine. In this case gonadotropin excretion was especially high because the patient had multiple metastases.

These examinations indicate that the hyperemia hormone pregnancy test may also be used for the diagnosis of hydatidiform mole and chorionepithelioma. Unfortunately, we have not yet been able to test more than 3 cases because of their relative rarity. It should be stressed, however, that in the case of chorionepithelioma we obtained a positive hyperemia hormone pregnancy test with only 0.0003 cc. of urine. For the diagnosis of hydatidiform mole the excessive excretion of the follicle stimulating hormone is of diagnostic value[22] and it is questionable whether the ordinary hormone pregnancy test can be dispensed with for this purpose.

IS THE HYPEREMIA TEST SUFFICIENT?

The hyperemia test in the rat is adequately accurate for the determination of pregnancy but is not sufficient for the examination of disturbed pregnancy (ruptured extrauterine pregnancy, threatened, incomplete and missed abortion). In these cases the titer of chorionic gonadotropin in the urine is on the decrease; the luteinizing hormone ("prolan B") is not detectable any more, whereas the follicle stimulating hormone ("prolan A") still is. From the presence of the follicle stimulating hormone the clinician can deduce that there is still some placental tissue in contact with the circulation. In table 1 are shown 4 cases of disturbed extrauterine pregnancy in which the A reaction was positive. This was reason enough for us to suspect a tumor protruding near the uterus to be an extrauterine pregnancy, which was confirmed by laparatomy (Z). Out of 13 cases of abortion 9 were A positive, which also proved to be of importance for diagnosis. Furthermore, it should be remembered that the presence of the follicle stimulating hormone is an important clue in cases of polyhormonal disturbances and malignant tumors. In hydatidiform mole and chorionepithelioma the same holds true, as already mentioned.[22]

In the light of our recent experience with the pregnancy test, the importance of knowing the history of the patient cannot be overemphasized. When it is a question of the simple determination of pregnancy, the hyperemia hormone pregnancy test in the rat, as described, is sufficient. If there is a suspicion of disturbed pregnancy, e. g. bleeding of uncertain cause in a woman, the ordinary hormone pregnancy test cannot be dispensed with. It is especially valuable in the diagnosis of disturbed extrauterine pregnancy and the differential diagnosis between bleeding from soft myoma and from disturbed intrauterine pregnancy.

We are at present developing the follicle stimulating hormone (A) test in the rat, so that in future we hope to be able to use the rat test also as an alternative in cases of disturbed pregnancy. We have for this purpose added 2 more rats to the 3 rats used for the six to twenty-four hour test. They are opened after four days. One receives 2 cc. of urine twice and the other 1 cc. twice administered at a one hour interval. They serve to check the six to twenty-four hour test and to determine excretion of follicle stimulating hormone. (The results with this technic have been based until now on only 80 patients.) When both rats give positive reactions for the luteinizing hormone (anterior pituitary reaction III) they confirm pregnancy in the patient, and when both are negative they confirm the absence of pregnancy. When both are positive for the follicle stimulating hormone only (vaginal estrus, anterior pituitary reaction I) the possibility is hinted at of functional disturbances (polyhormonal amenorrhea, climax), tumors and disturbed pregnancy (ruptured extrauterine pregnancy, threatened, missed or incomplete abortion). When the rat with the larger dose (2 cc. twice) is B positive and that with the smaller dose (1 cc. twice) is A positive but B negative, a significant decrease in the concentration of chorionic gonadotropin is indicated. This occurs mostly in cases of disturbed pregnancy, as mentioned, and occasionally in tumors. This finding should stimulate the clinician to make another proper examination of the patient.

SUMMARY

1. Chorionic gonadotropin brings on, in the ovary of rodents, the well known anterior pituitary reactions (I-III). The earliest of these reactions is hyperemia of the ovary of the infantile rat. Hyperemia occurs as early as two to six hours after injection, reaches its peak after twenty-four hours and disappears in forty-eight hours. Hyperemia is the first stage of anterior pituitary reaction II, its second stage being the follicle hemorrhage (blood dot).

2. Hyperemia of the ovary does not appear in all rodents in a similar way. The infantile rat is the best reactor, whereas the infantile mouse and rabbit cannot be used.

3. As regards the hyperemia effect (anterior pituitary reaction II) in the rat, the gonadotropic hormone from the anterior pituitary lobe is the most active, pregnant mare blood gonadotropin is the least active, and the activity of chorionic gonadotropin from pregnancy urine lies in between. With chorionic gonadotropin hyperemia may be produced with the same amount of hormone which evokes vaginal estrus; the amount used for luteinization is about three times as great.

4. Hyperemia is apparently evoked by the luteinizing hormone, while the follicle stimulating hormone seems to play a role as an augmenting factor.

21. In our animals the hyperemia unit (anterior pituitary reaction II in the rat after one injection) approximately equals the blood dot and luteinizing unit (anterior pituitary reactions II and III in the mouse after six injections), but it is possible that this relation differs with different strains of animals.

22. Zondek, B.: Gonadotropic Hormone in Diagnosis of Chorionepithelioma, J. A. M. A. **108**: 607 (Feb. 20) 1937; J. Obst. & Gynaec. Brit. Emp. **49**: 397, 1942.

5. The hyperemia hormone pregnancy test in the infantile rat may be used for the early determination of pregnancy. The time factor plays a decisive part. In the two hour test the reaction is extremely unreliable, so that pregnancy can be diagnosed in only 69 per cent of the cases and with the six hour test in 92.2 per cent, whereas the twenty-four hour test is reliable in 100 per cent of the positive cases. There may be, however, occasional positive results with the twenty-four hour test with nonpregnant patients (tumors). They bring the error in the twenty-four hour test to 1 per cent (tested in 300 cases). The two and six hour tests can be relied on if the result is positive. When it is negative, the result of the twenty-four hour test must be awaited.

6. The hyperemia test in the infantile rat is suitable in undisturbed pregnancies. In cases of disturbed pregnancy (ruptured extrauterine pregnancy, threatened, incomplete or missed abortion, hydatidiform mole and chorionepithelioma) the ordinary hormone pregnancy test cannot be dispensed with for the time being.

7. The hyperemia hormone pregnancy test in rats is based on the appearance of anterior pituitary reaction II, which is one of the decisive principles used in the ordinary hormone pregnancy test.

Clinical Notes, Suggestions and New Instruments

THE PREPARATION OF POTENT ANTI RH TYPING SERUMS BY INJECTION OF RH POSITIVE BLOOD INTO PREVIOUSLY ISOIMMUNIZED INDIVIDUALS

JOSEPH M. HILL, M.D.; SOL HABERMAN, PH D., AND ALFONSO VELEZ OROZCO, M D
WITH THE TECHNICAL ASSISTANCE OF
SHIRLIE TALLAL TRUBY, B.A
DALLAS, TEXAS

The experience of the William Buchanan Blood, Plasma and Serum Center with routine Rh typing since May 1944 has led to the conviction that this additional routine service is essential for transfusions of maximum safety.[1] It also appears that infant mortality due to hemolytic disease of the newborn (erythroblastosis fetalis) can be decreased through the additional information acquired from routine Rh typing of all obstetric cases and newborn infants; also routine Rh typing should be available to military services, first, because in the great number of whole blood transfusions now being given there is increased opportunity for Rh negative individuals to be sensitized so that later transfusions may be dangerous and, second, the necessity for multiple transfusions following severe battle injuries increases the opportunities for isoimmunization with the Rh antigen and resultant transfusion accidents.

The chief problem in routine Rh typing is to secure a sufficient and continuing source of potent antiserums. Initially a routine Rh typing service was established in this center largely on the basis of 200 cc. of very high titer plasma obtained from the mother of an erythroblastotic child. With a titer of 1:640 this plasma was theoretically adequate to perform approximately 80,000 tests. Actually, demands from other institutions and quantities used for investigative purposes together with the steady drain of routine testing (over 8,000 tests to March 1945) indicated that some additional or more potent source of Rh antiserums was necessary. We believe that the injection of Rh positive cells in properly selected previously isoimmunized individuals as described in this report may answer this need.

The necessity for using human sources for Rh antiserums results from the fact that sufficiently potent serums are difficult to produce in animals, are small in quantity and, because of low titer, cannot be increased appreciably by dilution. Landsteiner and Wiener [2] first produced an antibody in rabbit serum by intravenous injection of Macacus rhesus erythrocytes. This antibody was designated anti-Rh. Later, Landsteiner and Wiener [3] described the production of antiserums by injection of Rhesus red cells into guinea pigs. Only occasional pigs produced serums of effective potency, and all workers attempting to obtain serum by injection of animals have had difficulty in obtaining high titer useful antiserums. Our own results with animals have thus far been equally disappointing. By contrast, human antiserums obtained from mothers of infants with hemolytic disease have often proved very satisfactory. In fact, even in the original case of isoimmunization reported by Levine and Stetson [4] the mother's serum could be used to differentiate between compatible and incompatible donors, 21 out of 104 being compatible. It seemed logical to go a step further and by intravenous injection of Rh positive cells to raise the titer of the serum from mothers delivered of erythroblastotic infants. This procedure could be used either shortly after delivery to produce higher titers or at later intervals to produce satisfactory antiserums through the anamnestic reaction. Obviously, the possible risks incurred by such blood donors had to be carefully weighed and the decision made in consultation with the patient on an individual basis.

REPORT OF CASES

CASE 1.—A white woman aged 22 of type A, Rh negative, was admitted to the obstetric service Dec. 10, 1944 with the history of an uneventful delivery of 1 previous normal boy eighteen months before (Rh positive by present tests). On the day of admission an apparently normal Rh positive male child was delivered. One day later this baby developed icterus with erythroblastosis but recovered after transfusions of Rh negative blood The mother showed Rh antibodies in a titer of 1:4 with a positive blocking test.[5] A series of small intravenous injections of Rh positive blood was started six days after delivery. The initial dose consisted of 1 cc. of the infant's cells (type A, Rh positive) in 1 cc. of citrate saline solution. Two days later the same procedure was repeated and a sample of blood was taken for titration. Positive agglutination was found at 1:8 dilution, doubtful at 1:16. Blocking antibodies were demonstrated, however, at 1:16 and doubtful at 1:32. An additional injection of 1 cc. of baby's blood was given on the next day and a titration one day later showed an antibody titer of 1:8 but no blocking antibody. Four days later (eight days after the initial blood injection) an injection of 4 cc. of Rh positive blood and 1 cc. of citrate saline solution was given in the morning. A moderate febrile reaction occurred the same afternoon with temperature maximum of 101 F. The blood for this last injection was not taken from the infant but from a person whose erythrocytes agglutinated most strongly with the antibodies already present in the patient's serum. A titration three days after this last injection showed a titer of 1:2,048 and a blocking antibody titer of 1:8 using type O, Rh positive cells of one of us (S. T. T.). A titration with different type A, Rh positive erythrocytes (E. B.) showed a

titer of 1:512 with no blocking antibodies demonstrated with these red cells. Two days after this test (five days after the last and thirteen days after the initial injection) 500 cc. of blood was collected from this patient and then transfusion of 1,000 cc. of Rh negative blood was given to compensate for blood drawn and for a slight anemia.

CASE 2.—A white woman aged 29 of type A, Rh negative, was admitted to the obstetric service with the history of having had 1 normal male child approximately three years earlier. A full term Rh positive female infant was born jaundiced and anemic but responded well to transfusions of Rh negative blood and recovered. The mother showed antibodies in her serum at a dilution of 1:1,280. Sufficient blood was collected from the patient before leaving the hospital to yield 200 cc. of plasma. This plasma, having a specificity of approximately 85 per cent (i. e. this plasma agglutinates the erythrocytes of 85 per cent of the general population) was used as the basis for starting our routine Rh typing service.

The patient returned eighteen months later and testing of her serum showed that an anti-Rh titer of 1:64 was still present. Injections of Rh positive blood to produce a higher titer typing serum was agreed on after discussion of the procedure and its consequences with the volunteer. An initial intravenous injection of 2 cc. of type O, Rh positive cells (E. W.) mixed with 1 cc. of citrate saline solution was given. On the next day a similar dose of Rh positive, type O cells (S. T. T.) was given. A test titration of the fifth day showed a titer of 1:128 (against S. T. T. cells). On the eighth day a sample was taken for titration and 5 cc. of Rh positive blood (S. T. T.) mixed with 20 cc. of saline citrate solution was slowly given. No ill effects were noted. The serum from this sample titrated at 1:512 against known Rh_o' and Rh_o'' cells. Another test titration on the tenth day showed a titer of 1:640. Blood had to be collected on the twelfth day because the patient had to leave the city. At this time 750 cc. of blood was collected and replaced by a transfusion of 500 cc. of Rh negative blood without reaction. This blood yielded 325 cc. of serum with a titer of 1:2,560, which dropped to 1:2,048 (against known Rh_o', Rh_o'' and S. T. T. cells) after removal of anti-B agglutinins by absorption of B Rh negative cells. An additional 200 cc. of saline washings of the blood clot yielded a useful titer of 1:512. This serum has been dried in convenient small quantities by the adtevac process in glass ampules and vacuum sealed.

The antiserums from each of these volunteers was tested for specificity by typing a consecutive series of mothers and babies in the obstetric service. The serum from case 1 was run parallel with original plasma taken from case 2 following delivery, but before injection of Rh positive erythrocytes. From case 2 after injection of the positive cells the serum was also tested on 271 mothers and babies but not run parallel with the other serum and plasma. These results are shown in the accompanying table.

Results of Testing Antiserums for Specificity

	Total Blood Tested	Rh Negative	Rh Positive	Per Cent Reactivity
Case 1 serum	610	83	527	86.39
Case 2 plasma	610	96	514	84.26
Case 2 serum after injection of red blood cells	271	38	233	85.97

COMMENT

Because of the possible serious consequences of Rh isoimmunization, it is important to decide what criteria should be used in choosing volunteers for production of Rh typing serums by injection of Rh positive cells. First we believe that only those who have been previously isoimmunized (through pregnancy or prior transfusions) should be used. A woman once sensitized to the Rh antigen may find it impossible to have a normal child by an Rh positive husband even though sensitized long before, for example, by transfusions in early childhood. Of course either sex, if previously isoimmunized, faces severe, even fatal, reactions if given transfusions of Rh positive blood. The aforementioned risks which would be deliberately incurred by injecting Rh negative volunteers not previously sensitized probably are not justified even though it appears that a relatively small proportion of Rh negative people are capable of isoimmunization. On the other hand, little if any additional danger is added by increasing the antibody titer. These sensitized individuals in any event should be warned against ever receiving Rh positive blood by transfusion, and mothers who have had an erythroblastotic child or had antibodies in their serum have little chance of having additional normal Rh positive children. Later children, if Rh negative (by another husband or heterozygous husband), would not be affected regardless of anti-Rh titer. Of course, if routine Rh typing should be done universally, the risk of transfusion accidents would be largely eliminated.

In the light of these considerations, we believe that previously sensitized men and women volunteers who understand the essential consequences of the procedure both adverse and beneficial should be accepted for preparation of Rh antiserums as herein described. In the case of women it might be well to accept only those who already have children and especially those not desiring more.

If some risk is still incurred it may well be justified in view of the possible life saving service rendered. For example, the 325 cc. of serum from case 2 alone, because of its high titer, is capable of performing over one-fourth million tests if used at a conservative dilution of 1:40 and assuming 20 tests per cubic centimeter of serum. The problem of producing sufficient anti-Rh testing fluid for routine testing thus appears largely solved. In fact, steps have already been taken by the blood center to make routine Rh testing possible in the obstetric and transfusion services in all the main hospitals of Texas. Furthermore, the use of a strongly reacting testing fluid makes this admittedly delicate test easier to read correctly.

The results obtained by injection of such small amounts of Rh positive blood indicates that the Rh factor may behave as a reasonably strong antigen under suitable conditions. In both cases relatively small total doses of blood were used (7 cc. and 10 cc.) because of uncertainty about the effect on the patient. In view of the reaction in case 1 to 5 cc. we believe larger doses should be used with extreme caution, although the reaction may have been due to pyrogenic substances rather than to hemolysis. In choosing the red cells to inject it seems that the cells of the baby would be most certain to produce further antibodies. On the other hand it may be more difficult to obtain the babies' cells, and in addition these cells may be greatly diluted with transfused Rh negative blood if the infant has been treated for erythroblastosis. Under these circumstances the dosage would be difficult to determine. An alternative would be to use the father's cells if otherwise compatible or to use Rh positive erythrocytes which have been demonstrated to react most strongly with the antibodies already present in the serum of the mother (i. e. cells of same specificity, for example Rh_o'' cells for Rh_o'' antibodies).

In testing the titers of the Rh antiserums the same cells should be employed that were used as the antigen. For the determination of the end point of titration precise measurement of the dilution should be made, using accurate pipets or burets and starting the initial dilution at a fairly high value.

In addition to the value of a high titer in making more tests and clearer tests possible, it should be noted that such serums withstand the necessary manipulations of adsorption with red cells or neutralization with type specific substances without serious reduction of potency. This is important in producing a serum free of interfering anti-A, anti-B or other agglutinins. High titer Rh antiserums also present interesting possibilities for production of subtype antibodies by adsorption

of unwanted fractions by known suitable Rh positive erythrocytes. Furthermore, the choice of different Rh antigens (subtypes) for isoimmunization made possible by our procedure opens up new opportunities for producing specific subtype antiserums.

Because of the value of anti-Rh serum and since there is some evidence that a preservative such as merthiolate may interfere with its reactivity, potent Rh antiserums should be dried from the frozen state in small quantities so that the typing material need not be held in the fluid stage for any length of time.

PREVENTION OF UNINTENTIONAL ISOIMMUNIZATION OF THE RH NEGATIVE FEMALE POPULATION

PHILIP LEVINE, M.D., LINDEN, N. J.

The obstetric history of mothers of erythroblastotic infants reveals that this condition, as a rule, does not occur in the first born. Frequently the first one, two or more Rh + infants are normal. From the point of view of isoimmunization, it is clear that one or more pregnancies with Rh + offspring are required to induce a state of isoimmunization sufficiently intense to produce the hemolytic condition in the following Rh + infant.[1] In other words, the first one or more pregnancies serve the same preparatory function as repeated uneventful transfusions of an Rh — male patient with Rh + blood.

The study to be presented indicates the importance of prevention of the deliberate isoimmunization of the Rh — female population, including even the newborn infant, by transfusions with Rh + blood.[2] Evidence is produced to indicate that even the first born is frequently lost as a result of previous immunization by transfusions. The indications are that once an Rh — individual is immunized, that person remains immunized for the remainder of his or her natural lifetime.[3] Although the immediate evidence of isoimmunization, the presence of Rh antibodies, is evanescent, the tissues responsible for the producton of antibodies, i. e. the cells of the reticuloendothelial system, are capable of responding far more rapidly to the same immunizing stimulus even many years after the initial response. In other words, immune antibodies are demonstrable only for comparatively short periods in contrast to the immunized state, which is persistent for a period of many years and to all intents and purposes must be considered permanent.

Several examples of the long duration of the immunized state produced by several transfusions or by pregnancy or a combination of the two factors have been reported previously.[4] These cases were studied because of the unexpected occurrence of severe transfusion reactions. Recently I studied the blood of an Rh — woman aged 20 whose first pregnancy resulted in the most severe form of erythroblastosis fetalis, i. e. fetal hydrops. Because this severe condition in the first born is remarkably rare, it was suspected that the patient was immunized previously by transfusion. This could be verified because the patient at the age of 6 was transfused several times with her father's blood.

Accordingly, the vast material that I have studied in the past few years was analyzed for the frequency of erythroblastosis fetalis in the first born in two groups of cases: (1) women giving a history of transfusions preceding their first full term pregnancies with Rh + fetuses and (2) a control group not immunized previously by transfusions. These findings, limited to Rh — women, are presented in the accompanying table.

From the Ortho Research Foundation.

1. Levine, P.; Burnham, L.; Katzin, E. M., and Vogel, P.: Am. J. Obst. & Gynec. 42: 925, 1941.
2. Levine, P.: Human Fertil. 9: 65, 1944.

4. Levine, P., and others, in Mudd, S., and Thalheimer, W.: Blood Substitutes and Blood Transfusion, Springfield, Ill., Charles C Thomas, 1942, p. 309. Weiss, Charles: California & West. Med. 60: 59, 1944. Levine.[3]

These findings indicate that erythroblastosis fetalis is almost twice as common in the group of Rh — women previously immunized by transfusions. Still more striking, however, is the high incidence of fetal death in the first born in the transfused group. Obviously the transfusions induced an immunized state of the antibody producing cells, so that many years later with the very first pregnancy there already was sufficient intrauterine blood destruction to produce fatal forms of erythroblastosis fetalis.

These findings support the recommendation that no transfusion be given to young women, girls or even female infants unless tests for Rh are carried out. All those found to be Rh — must receive Rh — blood. One or more transfusions of Rh + blood administered to an Rh — female infant may prevent her, many years later, from having one or more normal Rh + infants. On a theoretical basis, this possibility has already been mentioned.[5]

The question arises as to the mechanism responsible for erythroblastosis fetalis in the first born in the absence of previous transfusions. Presumably, this group of Rh negative mothers is selected because of their ready susceptibility to respond to antibody production. The possibility exists, however, that the immunization in these women may have been initiated many years previously by the common practice of administering blood intramuscularly, particularly to the newborn. Since the introduction of the use of vitamin K this procedure, by and large, has been abandoned. The objection may be raised that small quantities of blood will not immunize. There is, however, a good deal of evidence in immunologic literature to

Erythroblastosis Fetalis in the First Born of Rh Negative Women

	Transfusion History	
Severity of Disease	+	—
Mild	1	4
Severe	5	4
Fetal death	10	1
Number of cases	16	9

indicate that unbelievably minute amounts of blood or other antigens suffice to induce immunization. It has been calculated[3] that the passage of only 0.13 cc. of fetal blood is required to immunize the Rh — mother. Pregnancy and intramuscular injection of blood provide conditions favorable for immunization, i. e. minute quantities of blood acting over a long period.

In a sense, the conditions for isoimmunization are satisfied in every blood transfusion. It is known that transfused compatible blood survives for a period of one hundred to one hundred and fifty days. Because blood, at any particular time, consists of a red cell population of varying age, there is always a certain small amount of the older red blood cells ready for destruction and, hence, for immunization.

As a rule it is difficult to obtain a history of intramuscular injection of blood, but in view of its routine and indiscriminate practice in the past this procedure must be seriously considered as the source of isoimmunization in Rh — individuals, even in their infancy or their neonatal period. In short, it is necessary to avoid this form of therapy in Rh — girls or women unless Rh — blood is used.

Incidentally, the so-called biologic test to detect Rh incompatibility, as recommended recently, will also serve to immunize.[6]

The unintentional immunization of the Rh — female population by transfusion or intramuscular injection of Rh + blood can now be prevented. This simple measure by itself should reduce the incidence of erythroblastosis fetalis, especially in its more severe forms.

The Council on Physical Medicine has authorized publication of the following article.

HOWARD A. CARTER, *Secretary.*

BODY MECHANICS AND POSTURE

K. G. HANSSON, M.D.
NEW YORK

Physical medicine is a more correct term than physical therapy when such a subject as body mechanics is included. By body mechanics is meant both the static and the functional relationship between the parts that make up the body, and the body as a whole. The study of body mechanics is of as much value in prevention as in the cure of pathologic conditions of the body. The White House Conference on Child Health and Protection made the guarded statement that "it is reasonable to believe that 75 per cent of the youth of the United States exhibits grades of body mechanics which are imperfect." In zoology and botany one finds more definite information of the relationship of appearance and function. Every one can recognize a sick dog because of the dejected position of his body, and all understand when a plant is failing because of its appearance. Every one in the great army who combats human ailments must be interested in the prevention as well as in the cure of disease. Therefore every one should have some knowledge of body mechanics, because it has its application in all specialties.

Body mechanics may be discussed under the following headings:

I. The relationship of posture to health.
II. Evolution of Posture. (The development of our present body, the anthropology of the various systems and the phylogenesis of their functions, which must be analyzed by body mechanics in its broad sense)
III. Posture standards and treatment.
IV. Body mechanics in various specialties (orthopedics, pediatrics, obstetrics and gynecology, internal medicine).

I. RELATIONSHIP OF POSTURE TO HEALTH

Our body build is largely inherited, just as the shapes of our features. Our features cannot be changed, and neither can our body build However, the interrelations of the 200 bones or more which are joined together by ligaments and acted on by muscles are subject to the same mechanical laws and forces which control any other machine. The maintenance of body function, of health, of life itself is concerned with balance between antagonistic forces. Balance is the motivating force in good posture, if we lie down, walk, play baseball, ski or swim. When this balance is disturbed by fatigue, accidents, disease or occupation, the efficiency of the body as a machine is lowered. It may be said that physical laws applied to our body mechanics give the answer to the question if posture is related to physical health.

Even mental health is affected by posture. Our sense of well-being and our emotions are often mirrored in our posture. The psychologist William James once wrote that correct posture kept up the spirits and tended to banish fear and depressing thoughts. All artists, be their medium clay or oil, have always associated alertness with good posture and depression with a slouch.

There are many clinical evidences for the effect of poor body mechanics and health. It is true that we all know of persons with poor body mechanics enjoying apparently perfect health. It must be remembered that our body is wonderfully adjusted to compensate for partial deficiency and also that many persons are satisfied with second or third degree health. The medical profession was slow in accepting poor posture and poor health as one of cause and effect. In 1740 Nicholas Audry taught that many illnesses in children had their origin in imperfect body mechanics. A generation ago the foundation for our present conception of body mechanics and health was brought out by Goldthwait and continued by Osgood. All surveys of posture in our primary schools show less illness, as proved by absences among children taught good body mechanics. Similar surveys in our colleges indicate a definite correlation between good functional health and good body mechanics.

Internists report improvements in arthritic patients when their body mechanics is corrected.

Miller and Polak have shown a definite relationship between posture and health in patients with dysmenorrhea and backache.

Orthopedic surgeons have overwhelming evidence for the importance of body mechanics both as a preventive and as a curative agent. Foot strain, knee pain, backache and many other complaints come daily under their observation and may be eliminated or improved by correction of body mechanics.

II. EVOLUTION OF POSTURE

Comparative anatomy teaches much about the assumption of the erect posture, and to understand body mechanics, one has to consider the alterations that the human anatomy underwent when the body was changed from quadruped to biped. This alteration in posture caused very definite changes not only in the shape and actions of bones and muscles but also in the workings of the circulatory, digestive, endocrine and nervous systems. Further analysis disclosed changes in the histologic structure of the tissues and in the chemistry of the body.

(a) *The Skeleton.*—When strolling through a museum of natural history and viewing the skeletons of reptiles, birds, dogs, anthropoid apes and man one can easily visualize what kind of locomotion such a skeleton performed. The reptile's skeleton was made for swimming and crawling. The forelimbs were developed to raise the animal off the ground and into the air. The hind legs were developed together with the foreleg, and there was the quadruped. The anthropoid apes began climbing trees and holding the body erect at intervals, at least, and man represents the highest development in biped skeletons. The spine changes little, but the head and extremities show pronounced changes. The skull becomes bigger and heavier, especially the frontal and parietal bones. This heavier head is balanced on the cervical spine with the convexity forward. The scapulas are displaced downward, giving a longer neck with more mobility, which compensates for the fact that the eyes are directed forward. The keynote of construction in the shoulder and upper extremity is mobility and speed rather than support. The human clavicle is long in order to hold the shoulder girdle away from the sternum. Thereby the clavicle becomes parallel to the posterior ribs rather than to the lateral ribs as in the quadruped. The glenoid fossa is

small, allowing free movement of the humerus, and this movement is restricted and protected by the acromial process. The so-called carrying angle at the elbow, the slightly separated bones in the wrist and the separation of the thumb from the other fingers are characteristic of the human skeleton.

The biped thorax has its greatest diameter from side to side, with a wide costal angle. The first rib is almost horizontal, and the last rib is nearly vertical and may produce periosteal irritation with the transverse process of the vertebrae.

The spinal column, originally intended for swimming and crawling, presented a convexity posteriorly. The baby is born with a one curve spine, but when it can raise its head the cervical curve develops, and when it can stand the lumbar curve is formed. The sacral and coccygeal vertebrae help to reinforce the pelvis. The spine, with its strong vertebral bodies, its numerous processes and the intervertebral cushion-like disks, is a marvel of elasticity and strength. There are many variations of the spine, both as to number of vertebrae and as to degrees of the curves. They may be regarded as evolutionary progression or retrogression. Thus a lumbar spine of four vertebrae may be considered as a progression and the one curve spine in spondylitis as a retrogression. The force of gravity, transmitted through the spine, is received by the sacrum at an angle. The anterior surface of the sacrum is broader than the posterior surface, and therefore a certain amount of anterior-posterior motion is possible. However, any displacement between sacrum and iliac bone is questionable. The lumbosacral articulation is more commonly involved in pathologic conditions of the lower part of the back. Here a freely movable spine meets a rather rigid pelvic girdle. In the quadruped the sacrum and the ilium are long, narrow bones, while in the biped there are broad, flaring sacrum and iliac bones. These, together with ischial and pubic bones, support the viscera above, protect the reproductive organs within and serve as muscular attachment for the powerful walking muscles. A plane laid through the symphysis pubis and posterior superior iliac spine is at about 40 degrees with the vertical frontal plane and at about 50 degrees with the horizontal plane. The analyses of these planes are important when dealing with body mechanics, because the pelvis works as a double lever with the fulcrum in the hip joint, and any changes in these planes have an important bearing on the position of the spine.

The angle of the neck of the femur is depressed from 150 degrees in the quadruped to 125 degrees in adult man. The head and neck are rotated forward, so that on standing most of the head looks forward. The femur is bowed forward in man, and it was from the study of the histologic construction of the femur that Wolff evolved his law of functional adaptation. Most quadruped knees are held in flexion, while the human weight bearing knee supports the body weight in extension. The medial condyle of the femur is more distal than the lateral one, which projects forward slightly. This projection prevents the slipping of the patella when the quadriceps contracts. The line of gravity falls slightly to the outside of the middle of the knee joint as the result of the valgity. This is even more pronounced in knock-knees, while in bow legs gravity falls toward the median side. Knock-knees are more prone to give trouble than bow legs and often show ligamentous strains and patellar deviations.

It might be suspected that the change to the erect posture would be pronounced in the foot, which is the point of contact between the skeleton put on end and the ground. This is the case. The tarsal and metatarsal bones are in closer apposition than are the corresponding quadruped bones. The development of the horizontal and transverse arches are seen. The big toe is held in extension and close to the other toes, which are held in flexion. The inverted foot of the tree-climbing ape is now everted, and the heel, the outer edge of the sole, the distal ends of the metatarsals and the entire hallux are developed for weight bearing purposes.

(*b*) *The Muscular System.*—The changes in the skeleton are mainly determined by muscles. The aforementioned skeletal changes are therefore to be considered in the light of trophic stimuli of function.

The quadruped holds up his head by means of a powerful ligamentum nuchae, which is aided by strong posterior neck muscles. In the human being the skull is delicately balanced on the cervical spine, the ligamentum nuchae is rudimentary and the neck muscles act like guy ropes. It is easy to understnad that if the human construction of head balancing is forced to hold the head in the quadruped way an undue strain is put on the posterior neck muscles. This is what takes place when one sits in a slouching position with the chin touching the chest, and it will result in a myositis that is often encountered and not easily dealt with unless the position of the head is corrected.

The trapezius, the levator scapulae and the rhomboids help to hold the scapulas in place. When the shoulders are allowed to slide forward and down, pressure symptoms may develop from the cervicobrachial nerves and the blood vessels.

The development of the deltoid in man is related to the increased motion in the glenoid fossa. This has been obtained at the expense of power and stability. One recognizes this in the whole upper extremity. A phylogenic study of the upper extremities shows that abduction, external and internal rotation in the shoulder joint, supination and pronation in the forearm, and apposition of the thumb to the other fingers are more recent developments. It is also of interest to speculate on the fact that these phylogenically younger movements are the first ones lost and last ones regained in many pathologic conditions. These are probably examples of specific morbidity.

An analysis of the mechanics of the extensors and flexors of the wrist and fingers, and the supinators and pronators of the forearm, will give a better understanding of traumatic external epicondylitis and will produce better results in its prevention and treatment.

The most pronounced change in the hip, when the anthropoid is compared with man, is the development of the abductors and the extensors. The opposing adductors and flexors were stretched when the biped position was assumed. Certain check ligaments reinforce the hip joint, the strongest one being the Y ligament, which becomes taut in the erect position. The specific morbidity based on phylogenesis should produce a flexion-adduction deformity in the hip joint following injury and disease, and this is exactly what takes place, and the comparatively new motions of extension and abduction are lost.

The biped locomotion, with flexion-extension of hip and knee, requires a more specialized quadriceps muscle than is seen in the quadruped. This muscle is the keystone of good walking. The coordinated flexion in the

hip and extension of the knee are made possible by the union of the rectus femoris and the vastus medialis and lateralis into one tendon, which is kept taut by the vastus intermedius. Any atrophy or diminished tone of this important muscle, which frequently follows pathologic conditions of the femur, or the knee, should be counteracted as early as possible, or the convalescence will be a very long one.

The knee extension is checked by the hamstring muscles, gastrocnemii and the popliteal ligaments, which latter reinforce the capsule. Any motions but flexion and extension are prevented by the lateral ligaments, the external and internal menisci and the crucial ligaments. The continued sitting position often leads to shortened hamstrings and gastrocnemii. In biped walking the body weight must be lifted and the foot must push the body off the ground. For this purpose the plantar flexors of the toes and foot are well developed. The thirty-eight articulations of the foot, supported by numerous ligaments, the anterior-posterior and lateral arches, all activated by long, slender, quick action muscles and coordinated with movements in knee and hip, make the human gait a great advancement over the shuffling locomotion of the anthropoid ape. The everted human foot, held parallel to the ground by the peroneal muscles, is far different from the grasping inverted foot of the ape, which type of foot is, however, found in the newborn baby up to the age of walking. The extension and eversion of the foot are undoubtedly phylogenically younger movements, and these functions are usually the ones easily lost in paralysis and neuritis from alcohol or metallic poison.

(*c*) *The Gastrointestinal Tract.*—The spine being the main support of the viscera, it is evident that the change to an erect position will affect the organs concerned with the maintenance of nutrition. If several rings are held on a horizontal stick they will hang free from one another, but if the stick is brought to a vertical position the rings will crowd on one another at the lowest point. This is what takes place, to some extent, in the change from a quadruped to a biped posture.

The stomach is attached to the diaphragm at the cardia, and the pyloric end is fixed to the body wall. The liver is partly suspended from the diaphragm and the transverse colon indirectly by means of the mesocolon. A great load is therefore carried by the center of the diaphragm, which, at least partially, is held through the right pericardium by the continuation of the cervical fascia. This fascia is attached to the cervical spine and mastoid process. One can understand, therefore, how flexion of the head and neck relaxes the cervical fascia, causing a ptosis of the viscera in the upper abdomen with pressure exerted on the organs in the lower abdomen and pelvis. Thus it is of importance to carry the chin in and the head back.

The stomach is usually placed well under the ribs of the left thorax. The upper part of the abdomen is roomy, but the lower part is very narrow because of the dorsal and lumbar curves of the spine, which give the maximum room above and the necessary support below. In fact, the anterior surface of the fifth lumbar vertebra is nearer to the anterior surface of the body than it is to the posterior surface.

The spaces flanking the vertebral bodies are filled with the psoas and quadratus lumborum muscles, which adds to the formation of a pear shaped abdominal cavity. The axis of this cavity to the perpendicular line is about 30 degrees. The pelvic cavity, which is directed down and back, has an axis which shows an inclination of about 60 degrees with the perpendicular line. Thus the two cavities are at right angles to each other, which, of course, counteracts the pressure downward. It is in this pear shaped abdominal cavity that the viscera are suspended.

The liver, spleen and kidneys rest on shelves reinforced by adipose tissue and suspended by fibrous bands. The small and large intestine are, in the main, suspended; the other viscera are shelved. In quadrupeds the whole large intestine has a mesocolon. The human ascending and descending colon is usually retroperitoneal and only the transverse colon has a mesocolon, which is suspended from the stomach. However, the quadruped mesocolon persists in about 30 per cent of human intestines, and this adds to the crowding of the viscera. It is evident that any deficiency in the suspension or in the shelves will produce a ptosis and will increase the kinks in the stomach as well as in the small and large intestine; these will have an unfavorable influence, in turn, on the digestion, assimilation and evacuation of the gastrointestinal tract. The congestion that results in the lower abdomen and in the pelvis may add to the factors producing leukorrhea in the female and prostatitis in the male, as well as prolapse of the uterus and anus.

(*d*) *The Circulation.*—The experiment in which a rabbit, when held erect, died from hemorrhage into the splanchnic area suggested that the circulatory system must have undergone certain changes when the biped posture was assumed. In the quadruped body the heart forces the blood stream in horizontal arteries and downward into the extremities, and the only veins that must sustain the weight and pressure of a vertical column of blood are those of the extremities and the intercostal veins. Therefore these veins are provided with valves.

In the erect posture the circulation becomes vertical. One can easily comprehend the increased work that the biped position threw on the cardiac musculature when it is considered that much of our rest is taken in the sitting position, which does not materially alter the load of the vertical circulation on the heart. The valves remain in the intercostal veins, although they have become unnecessary. The lack of such valves in the portal vein may be one of the contributing factors in hemorrhoids, pelvic congestion and ascites.

In the erect position the top of the head is about 40 cm. above the level of the heart, whereas in the quadruped the highest point is only about 15 cm. above the heart. The 25 cm. difference in the blood column represents about one twenty-fifth of an atmosphere. This is a definite addition to the quadruped blood pressure in the left ventricle, and the human organism is as yet but imperfectly adapted to it.

In addition, the arterial pressure is increased by gravity in proportion to the depth below the level of the heart, a depth which varies in both biped and quadruped positions. The portal circulation in the quadruped is at practically the same level as the heart. However, when the biped posture is assumed, the veins of the portal circulation lie 15 to 25 cm. below the heart level and the pressure in these blood vessels is suddenly raised from 15 to 25 mm. of mercury. On account of the high capillary pressure in man there is a greater tendency to edema of the dependent parts than in similarly constituted quadrupeds. This tendency applies especially to the portal area, where the integument is loose, there is double circulation and there is less capillary support.

(*e*) *The Nervous System.*—Although we have seen how the stimulation of muscular contraction affects the bone production, the question of how the osteoblasts rearrange their alinement and production can be answered only by scientific speculation, because of our limited knowledge of biochemical and electrothermic processes. However, it can be assumed that the nervous system plays some part in this trophic change because of the absence of functional response in cases of paralysis. It is therefore necessary to consider the changes into higher specialization of the nervous tissue which made the erect posture possible.

Judging by a child's first efforts to stand and walk, it seems that the erect posture was initially a very conscious effort and that it became less so by force of habit. To keep the skeleton on end in addition to all the other fields of activity thrust on the nervous system in the biped posture required an enormous increase in the size and specialization of this system.

For our purpose, the nervous system may be studied in relation to balance and muscle tonus. Balance is maintained by vision, the semicircular canals, the cerebrum, the cerebellum, and the deep-muscle sense, and deficiency in any one of these will stimulate the remaining ones to increased activity. This accounts for the superior muscle sense of the blind and is the basis of Frankel's treatment of locomotor ataxia.

By muscle tonus is meant the slight persistent tension which is characteristic of a healthy muscle. This tonicity is of the greatest importance in the maintenance of good body mechanics. Our knowledge of muscle tonus is rather limited, but it can be safely stated that the brain and the spinal cord, as well as the impulses arising in the muscles themselves, take part in the control, production and maintenance of the muscle tonus.

The brain's share in maintaining the erect posture may be deduced from the fact that mental concentration is more likely to produce correct posture than the lethargic state of the mentally deficient, among whom the quadruped posture is approached.

Experimental physiology demonstrates that a spinal frog, when suspended, will not take the attitude that gravity would impress on it. If one hind limb is extended gently it will soon draw up and resume the familiar crouching position. This posture of the limb is therefore the result of impressions continually ascending its proprioceptive nerves and exciting a tonic activity, which predominates in certain definite muscles. These posture reflexes, as carried out by the spinal cord, are segmental responses. They determine the relation of the limb to the trunk and, to a lesser degree, of the four limbs to one another. Experiments by Sherrington show that they are reflex in nature and are confined to the so-called antigravity muscles, which maintain the erect posture.

There is no doubt that some primitive posture reflexes are retained in man. We may even assume two posture centers, one in the upper cervical region and the other in the lumbar region. If the patient sits in a relaxed position, throwing the head back in extreme extension of the cervical spine, and from this attitude flexes the head forward so that the chin is pulled in, the result will be that the upper part of the body will assume the correct posture; that is, the back will straighten out, the thorax will be elevated and the scapulas will slide back and down where they belong. It is also of interest to note the postural reflex in the lumbosacral region. If a patient, lying face down, is asked to extend one of the lower extremities with the knee straight, a slight internal rotation of the extremity as a whole will result, with the foot in inversion. These two postural reflexes are of importance in the treatment of faulty body mechanics.

There is another side to posture reflexes, which has been studied by Magnus and de Klein. This deals with plants as well as with animals and their growth in relation to the environment. These investigators have shown that plants orient themselves in regard to gravity along well defined laws. This orientation is called "geotropism" and these same geotropic reflexes, or righting reflexes, are responsible for the ability that animals have to restore themselves in erectness. The phenomenon of a cat always alighting on its feet when tossed in the air is a well known example of this righting reflex.

Thus, in the final analysis of posture one arrives at the postural tone, which Sherrington has defined as "the reactions in which the configuration of the body and its parts is preserved, in spite of forces tending to disturb them, by the activity of contractile tissues, these tissues then functioning statically." This is the basis of physical education, the fundamental truth of which has been forgotten in the search for new and sensational systems.

(*f*) *The Endocrine System.*—Closely associated with the nervous control of body mechanics are the endocrine organs. Study of pathologic conditions of the pituitary gland leads to the deduction that there is some control by this gland over the growth of bones. The pituitary disease called acromegaly, in which the response of the osseous tissue to external stimuli is much increased, forms a beautiful example of Wolff's law. The voluntarily most active parts of the body are the lower jaw, the hands and the feet, and these parts are much overdeveloped in patients suffering from acromegaly.

From similar observations it is known that the overactivity of the thyroid gland produces a slender body type and that diminished activity of the thyroid produces the stocky type of myxedema. The same considerations apply to the thymus, ovaries and testis, all of which, to a certain extent, determine growth and nutrition.

III. POSTURE STANDARDS AND TREATMENT

The human body cannot be standardized, and individuals therefore cannot be made to conform to any definite preconceived standard physically, mentally or spiritually. Two contrasting body types must be recognized. There is the slender, high strung body build, often referred to as the carnivorous type. The other extreme is the stocky, placid type, also known as the herbivorous type. In between are all grades of variation. The posture standards illustrated here can be obtained from the Children's Bureau, Department of Labor, Washington, D. C. Although photographs and x-rays are valuable, they are not always practical. The physical examination should note the following:

1. Drop a tape measure from the mastoid process over the acromial process; it should hang over the greater trochanter and external malleolus. Also drop a tape measure from the posterior process of the seventh cervical vertebra; it should hang midway between the buttocks, the knees and the malleolii.

2. With the patient placed with his back to the wall and the feet 1 inch away, there should be only slight curves in the cervical, dorsal and lumbar regions. The chin should be pulled in over the sternal notch. The sternum should be the farthest forward part of the body, with the costal angle wide. The lower abdomen should be flat. The lower extremities should be

properly alined with the pelvis and the trunk. The femur and tibia should be perfectly opposed in the knee and this maintained by proper muscle balance, favorable to the weight bearing lines which protect the joint mechanism of the feet.

3. The body in motion must also be examined. Let the patient walk about the room and also jump on the right and left foot alternately. This will give an idea of the patient's motor habits.

TREATMENT

The causes of poor body mechanics may be considered under overactivity, insufficient or improper food, weakness against gravity and inherited or acquired faulty positions or movements.

Overactivity.—The rational treatment of overwork is, of course, rest. Hugh Owen Thomas said, many years ago, "The urging need of our art is the fact that much of our surgery is too mechanical, our medical practice too chemical, and there is a hankering to interfere, which thwarts the inherent tendency to recovery possessed by all persons not actually dying." Complete rest position should be approached as much as practically possible. This can be accomplished only on a hard mattress, with no pillow or a very small one. A small pillow under the knees will relax the iliopsoas and produce the anatomic rest position in the lower back, hips and knees. This position will rest the balancing mechanism, which means that the nervous and muscular systems cease working at high speed and have a chance to recuperate. The circulation becomes horizontal, with less demand on the heart and blood pressure. Gastrointestinal distress is often relieved by the recumbent position, respiration is easier and slower, and there is less strain on ligaments and cartilages.

Diet.—The quantity and quality of the food intake correspond to the fuel fed to a machine. We cannot expect function of the body unless properly supplied with carbohydrates for energy, protein for repair, and fat for insulation, minerals, vitamins and so on. The mechanical efficiency of the human body corresponds very well with a machine. In untrained men it is about 20 per cent, in trained men 25 per cent, and in outstanding athletes 33 to 41 per cent.

Support.—Constitutional weakness due to many causes, such as exhausting disease, operation, occupation and environment, often needs support. This support is often necessary in the interim between rest therapy and following the period of exercises. The shoulders may have to be held in a corrected position or the arches raised by means of adequate and inoffensive mechanical apparatus. However, it must be remembered that any kind of support is only a temporary remedy, except in the very aged, and should be discarded as soon as the muscles have regained their tone.

Postural Exercises.—Therapeutics in any field of medicine must be directed against the cause in order to be successful. If this is remembered when one is dealing with faulty body mechanics, it must be realized that exercises are not always the answer to poor posture. However, when exercises are indicated, they must be picked with discrimination. It must be realized that every effort to change voluntarily the relative position of the parts of the body is made through the use of the motor habits, which are expressed in the body alinement. To change posture, motor habits must first be changed in the motor pathways in the nervous system. With this change a different muscular response, both for balance and for movement, will occur. This is best accomplished by slow and oft repeated movements and the visualization of stabilized relationships of the various parts of the body during movement. The principle of posture exercises is best expressed by Cochrane: "If proper posture be maintained by conscious effort for a short time, then the increase of reflex tonus obtained by such posture will serve to maintain the proper attitude without the patient's requiring to give the matter thought and attention." The earlier such posture teaching occurs, the better, since age intensifies muscular habits.

BODY MECHANICS AT DIFFERENT AGES

Preschool Age.—This includes infancy to beginning school age. The baby's parents should be instructed in the symmetrical and nondeforming positions of recumbency as well as in the proper positions of holding the baby. Careful examinations of the baby's head following moving objects, of the grasping reflex of the hands, the kicking reflex of the lower extremities, the efforts at sitting, creeping and standing, will disclose possible abnormalities in growth and function. Some educators maintain that we waste five years of our lives being housebroken when much instruction could be given the child. Be that as it may, it seems only rational to watch this age group for tendencies to faulty body mechanics present in the parents and institute preventive measures. The type of exercises recommended are based on the primitive posture reflexes as advanced by Dr. Haynes. These postural reflexes were developed in the central nervous system before the frontal lobe of the cerebrum learned to think for man. They are the accumulation of associated movements.

Body Mechanics in Children of 5 to 12.—This is the age in which posture consciousness should be taught. However, it should not be associated with punishment. Instead, one should make use of plays and games so that the child will think of good posture with pleasure rather than with penal apathy. With girls, good body mechanics should be discussed in relation to dancing or the proper wearing of clothes. With boys, it is best taught in relation to sports. It is easy to bring out good body mechanics and to correct postural defects when describing the proper use of the body in baseball, swimming, skating and other activities. By combining postural correction with activities, the abnormal stiffness that our forefathers associated with correct posture is avoided and the easy, relaxed carriage is produced. Whenever possible, the natural posture reflexes should be the basis for the postural exercises in this age group. Corrective positions during rest periods are also recommended.

Body Mechanics in Adolescence (second decade).—In this age group body mechanics should be taught in relation to health. The school physician, the school nurse and the biology teacher should be included with the gymnasium teacher in the posture program. Efficiency in athletics should be emphasized in its relation to good body mechanics. A certain amount of corrective training should be introduced, based on hygiene, prevention of future defects and efficiency. There is no reason why such postural habits should not be part of the adolescent life the same as the care of the teeth and the skin, which has been generally accepted.

Body Mechanics in Adult Life.—In this age group we encountered forces of occupation that may alter our body mechanics. It is wise to analyze possible damage done to our body by inactivity at a desk, by monotonous movements repeated throughout the day, and by faulty

positions maintained in relation to machines or other unnatural static or dynamic functions that are imposed on civilized man. It is most important to counteract possible postural, occupational defects by exercises or games which will bring into use such parts of the body as are inactive or stretched during occupation.

IV. BODY MECHANICS IN VARIOUS SPECIALTIES

(a) BODY MECHANICS IN ORTHOPEDICS

No specialty comes in closer contact with body mechanics than orthopedics. I will mention only a few:

In congenital torticollis that has persisted for several years the child gets into the habit of photographing his surroundings on a certain field of the retina. The consciousness of such pictures is related to the child's appreciation of his position to his surroundings. Geotropic reflexes are built up which give the child the impression of being straight when his head is actually crooked, and vice versa. Therefore the cutting of the shortened sternocleidomastoid muscle and the shortened cervical fascia is only the beginning of the treatment. The patient's motor habits, based on the photograph of the surroundings on the retina and its interpretation, must be reeducated. This is a refined point in body mechanics that is most important.

The lateral curvature of the spine of the idiopathic type should be treated as a postural deformity, and symmetrical exercises should be instituted and carried on till the patient reaches at least his sixteenth year. Special attention to the patient's general health, as indicated by his vital capacity, is most important.

The use of postural exercises in low back pain has been confused a great deal. The confusion is due to the fact that the same exercises have been prescribed for all pathologic conditions in the lower part of the back. It should be emphasized that the exercises should be specific and should be based on the pathologic changes present. Dealings with low back patients are facilitated by the following clinical classification:

GROUP 1.—A more or less severe tear may occur, producing a hemorrhage and muscle spasm. The muscles most involved are the quadratus lumborum, gluteus maximus and gluteus medius. A myositis is produced, by laymen called lumbago. The exercises should be preceded by relaxation and the movements should consist of gentle, rhythmic changes of position of the spine, often repeated, but without great effort.

GROUP 2.—There is instability of the lumbosacral region due to congenital defects, an increased lumbosacral angle, spondylolisthesis and other mechanical weaknesses of the fifth lumbar region. Here an attempt should be made to strengthen nature's corset, represented by the abdominal muscles and the gluteal muscles, and correct the posture relation between the pelvis and the spine. A typical exercise is the pelvic roll.

GROUP 3.—Any muscle imbalance in one part of the body will result in compensating imbalance in other parts. A pronated foot, short heel cord, contracted hamstrings or spasm of the tensor fasciae and erector spinae are examples. This requires careful analysis of the body mechanics. The exercises should stretch the shortened muscles, and their antagonists should have concentric movements.

GROUP 4.—This group includes the arthritic spine, by far the most common pathologic condition in the middle and old age group of patients. Included here are synovitis, or arthritis of the small joints of the spine, and also fibrositis along the spine. In the early stages of these conditions it seems rational to try to prevent freezing of the joint motions. This is done by active and passive separation of the articulations. Traction on the spine, flexion forward and sideways, but especially extension, lying, sitting and standing as tall as possible, are the principles used.

GROUP 5.—Here may be gathered such specific cases as fractures and subluxations, synovitis of the sacroiliac joints and rupture of the nucleus pulposus. In this group the treatment is usually specific, but exercises are often used in the convalescent stage and for symptomatic relief. Attention to the general body mechanics should be observed. The proper alinement of the various segments of the body should be checked and possible spasm and muscle shortening counteracted.

(b) BODY MECHANICS IN PEDIATRICS

Pediatricians are usually concerned with children's diet, heart and lungs, tonsils and the infectious diseases of childhood. Body mechanics is seldom considered. The more importance laid on prevention, the more the responsibility is laid on the physicians who guide the child through the early life. Modern civilization has imposed many hardships on the human being, and a child's activities suffer more than an adult's activities. The child has less resistance. Let us, therefore, be kind and understanding, instead of nagging and punishing when we analyze defects in our children. The cause of the child's poor posture should be carefully diagnosed. It may be poor eyesight, poor nutrition or fatigue from various causes, such as constitutional disease or overactivity. There might be inherited weakness. It is evident that the treatment should vary. Exercises are not always indicated. However, when exercises are indicated they should be made a pleasure for the child and not an ordeal. The postural examination should be included in the physical examination and the following facts should be realized:

The feet are the foundation for weight bearing in standing and walking, and any defect in them will influence the rest of the body. If the feet are the foundation and the legs the supporting structures for the pelvis, we have the same mechanics as that of a bridge. The load of transportation varies, and stresses and strains must be met. The load that this bridge carries is represented by the trunk, which is held upright by the spine. In order to support the spine firmly, the pelvis should be placed in good mechanical relation to the spine. The spine, shoulders and arms can be likened to a coat rack, of which the main stem is the spine, the transverse hangers are the shoulders and the hanging coats correspond to the arms. If the spine is correct, the shoulders and arms will fall into the proper position. The head should rest with ease on the spine. This mechanical posture of the skeleton is maintained by muscles, which receive their tone from the nervous system, which in turn depends on the glands and the general nutrition and health of the body.

(c) BODY MECHANICS IN OBSTETRICS AND GYNECOLOGY

The specialties of obstetrics and gynecology seem far from the interest of body mechanics. However, statistics show that of 1,000 cases coming to a gynecologic clinic with the complaint of backache only 18 per cent were due to gynecologic disease and 82 per cent were postural in origin.

Dr. C. I. Miller of the State University of Iowa College of Medicine has published a study of young women in relation to dysmenorrhea. Among young women with dysmenorrhea he found 21.7 per cent with

good posture and 78.3 per cent with poor posture. In the group without dysmenorrhea, 73.9 per cent had good posture and 26 per cent had poor body mechanics.

It is only rational to believe that the great strain put on body mechanics in the pregnant woman should merit more careful consideration. The center of gravity is altered during pregnancy, greater strain is put on the weight bearing extremities, physical activities are restricted, muscles are overstretched, the nutrition is unbalanced, and most of the body systems are put to severe tests. Therefore more thought should be given to the reconstruction of the delivered mother. It seems perfectly logical that child bearing should be carried out without permanent deformity to the body by prescribing postural corrections at the earliest date that these can be taken without danger of hemorrhage or fatigue. Special care should be taken to insure return of normal tone to abdominal muscles, and proper weight bearing of pelvis and spine.

(*d*) BODY MECHANICS IN MEDICINE

The internist has been slow in accepting the place of body mechanics in his armamentarium of cures.

However, overwhelming evidence has been presented by Pemberton, Swain and others that the arthritic patient must be taught the proper use of his body as a whole as well as the various joints. Chronically ill patients may be much improved by instruction in body mechanics. Many can be helped by special substitution movements or mass movement exercises.

Visceroptosis has received much attention from the point of view of body mechanics. Rest, support, diet and the proper instruction in posture and proper postural function are generally accepted now as the foundation for the management of these patients.

Much of our training of spastic hemiplegia depends on the application of body mechanics.

Brachial neuritis, the scalenus anticus syndrome or the cervical rib syndrome are often postural in origin and can be relieved by correcting the position of spine, head and scapulas.

CONCLUSION

Body mechanics, or posture, assumes a greater importance and a wider application when viewed in the light of the foreging discussion. Certain conclusions also may be drawn:

1. The relation between health and body mechanics is soundly based on physical laws and on physiology. There is increasingly strong clinical evidence of posture and health being the cause and effect in many conditions.

2. The physician must be trained in the anthropology and phylogenesis of anatomy and function, so that he can analyze mechanical defects and prescribe proper treatment.

3. The question of posture standards is not satisfactorily solved, but a certain amount of literature can be obtained from the Children's Bureau, Department of Labor, Washington, D. C.

4. There is a definite need of more interest and more understanding of body mechanics among pediatricians, school physicians, gynecologists and internists.

Humiliating statistics were revealed by the universal draft in World War I, and it will be interesting to see if our present physical examinations for the draft will show any improvement. It is a pleasure to testify to the fact that our men in the armed forces today show the carriage and alertness of efficiency after even a short training period.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

VINBARBITAL SODIUM.—Sodium-5-ethyl-5-(1-methyl-1-butenyl) barbiturate.

Actions and Uses.—The actions and uses of vinbarbital sodium are somewhat similar to those of a barbituric acid derivative, having a short induction period and a moderate duration of action. It is used as a hypnotic and sedative. Like other barbiturates, this compound may cause side effects. These include epigastric discomfort, nausea, dizziness, pallor, apprehension, incoordination, weakness, headache and "hangover," while adequate dosage frequently causes a fall in blood pressure.

Dosage.—As a sedative, 32 mg. repeated three to four times daily; as a sedative and hypnotic, 0.1 Gm. to 0.2 Gm.; as a preoperative hypnotic, 0.1 Gm. to 0.2 Gm.; in psychiatric cases, 0.1 Gm. to 0.4 Gm.; for obstetric sedation and amnesia, 0.2 Gm. to 0.4 Gm., with or without scopolamine. Children must be given correspondingly smaller doses.

Caution.—Unbuffered aqueous solutions of vinbarbital sodium are not stable but decompose on prolonged exposure to the air. The powder is hygroscopic, and if capsules are broken or exposed to high humidity the contents are affected by both moisture and carbon dioxide.

Vinbarbital sodium occurs as a white, odorless powder, possessing a bitter taste; soluble in alcohol and water; slightly soluble in ether and chloroform. A 1 per cent aqueous solution is alkaline to phenolphthalein and has a p_H between 8.5 and 9.5.

Tests and Standards.—

To 5 cc. of a 10 per cent solution of vinbarbital sodium slowly add 2 cc. of dilute hydrochloric acid; allow the precipitate to crystallize, filter, wash and dry at 90 C.: the melting point of the vinbarbital is 161 to 163 C.

Transfer 5 cc. portions of a 10 per cent solution of vinbarbital sodium to two test tubes and to one add 1 cc. of mercury bichloride solution: a white precipitate results, soluble in 10 cc. of ammonium hydroxide; to the other portion add 5 cc. of silver nitrate solution: a white precipitate results, soluble in 5 cc. of ammonium hydroxide.

Dissolve 0.1 Gm. of vinbarbital sodium in 10 cc. of distilled water, add 1 cc. of sodium hydroxide solution and 4 drops of potassium permanganate solution: a green color develops in twenty seconds; add 5 cc. of dilute hydrochloric acid: the solution turns pink and a brown precipitate appears. Boil 0.5 Gm. of vinbarbital sodium with 5 cc. of 25 per cent sodium hydroxide: ammonia is evolved.

Acidify 40 cc. of a 10 per cent solution of vinbarbital sodium with dilute nitric acid and filter; separate portions of 20 cc. each of the filtrate yield no opalescence with 1 cc. of silver nitrate solution (*chloride*): no turbidity with 1 cc. of barium nitrate solution (*sulfate*); no coloration or precipitation on saturation with hydrogen sulfide (*salts of heavy metals*).

Transfer about 3 Gm. of vinbarbital sodium, accurately weighed, to a glass stoppered flask, add 50 cc. of anhydrous ether and shake for ten minutes. Decant the supernatant liquid through a filter and again extract the residue with 15 and 10 cc. portions of ether. Evaporate the combined filtered extracts to dryness in a tared beaker on the steam bath: the residue does not exceed 0.5 per cent.

Transfer about 0.5 Gm. of vinbarbital sodium, accurately weighed, to a separator, add 30 cc. of water and 10 cc. of dilute hydrochloric acid. Extract with seven successive portions of ether, filter the combined ethereal extracts and evaporate in a tared dish in a warm stream of air: the 5-ethyl-5 (1-methyl-1-butenyl) barbituric acid content is not less than 89.5 per cent nor more than 92 per cent. Evaporate the aqueous residue to dryness, add 3 cc. of sulfuric acid and evaporate the excess acid. Repeat, using 1 cc. of acid and incinerate the residue: the sulfate ash is not less than 27.5 nor more than 29.5 per cent.

SHARP & DOHME, INC., PHILADELPHIA

Capsules Delvinal Sodium: 0.1 Gm. and 0.03 Gm.

ANTI-ERYSIPELOID SERUM (See New and Nonofficial Remedies, 1944, p. 547).

The following dosage form has been accepted:

SHARP & DOHME, INC., PHILADELPHIA

Lyovac Antierysipeloid Serum: 15 cc. ampul-vials together with a 15 cc. ampul of distilled water and a 1 cc. vial of Normal Horse Serum (diluted 1 : 10) as test and desensitizing material.

U. S. patents and trademarks (see under Lyovac Immune Globulin).

THE THERAPEUTIC USES OF RADIOACTIVE PHOSPHORUS

Radioactive phosphorus has now been employed experimentally in treatment for about six years. The earlier work on this subject has been previously discussed in these columns.[1] Now a fairly extensive experience with this form of therapy has accumulated, especially for the leukemias and polycythemia vera. Recently Warren[2] reported results in the third large group of patients treated by this means since 1940 with radioactive phosphorus, consisting of 81 cases of leukemia, myeloma, Hodgkin's disease and polycythemia vera. The radioactive phosphorus employed in his series was prepared either by bombardment by the cyclotron of red phosphorus placed in an external target chamber or by the bombardment of an iron phosphide probe placed in the deuteron stream of the cyclotron just inside the port. Most of the cases of leukemia subjected to treatment had failed to respond to or were known to be refractory to prior roentgen therapy. Some of them were far advanced cases. Harm did not result from the administration of radioactive phosphorus in the doses employed. Furthermore, a limited number of cases "have done better" than would be expected with the ordinary means of therapy. However, if extensive leukemic infiltration of the marrow is present and there is little normal hemopoiesis, nothing is gained by treatment which destroys the leukemic cells. Under those circumstances the effect is merely to change the leukemia to an aplastic anemia. The basal metabolic rate, Warren says, is one of the useful guides to progress of the disease. This reflects the activity of the leukemic process and may be an even better index during the course of therapy than is the peripheral white blood cell count. Radioactive phosphorus, Warren concludes, provides a safe means of internal irradiation of leukemic tissue. Most patients respond with clinical and hematologic improvement, but the treatment must be considered palliative rather than curative, as the ultimate prognosis of leukemia remains grave.

Radioactive phosphorus in the treatment of polycythemia vera may now be considered of established value. Not only Warren but Hall and his colleagues[3] and others have obtained good results in the use of radioactive phosphorus for this disease. Hall and his colleagues employed this therapy for 12 cases of polycythemia vera over a period of two and a half years. Satisfactory remissions were induced in 8 of the 12 cases and incomplete remissions occurred in 2. Although the results were unsatisfactory in the remaining 2 cases, these investigators believe that this was due to inadequate dosage. In the group in which satisfactory remissions were obtained, both clinical and hematologic improvement occurred. The symptoms attributable to polycythemia vera disappeared and remissions lasting from eighteen to twenty-six months were observed in the favorable cases; 6 of the remissions had lasted for more than a year. The results obtained, the ease of administration (intravenous), the absence of radiation sickness and toxic symptoms and the concentrated effect of the irradiation on the cells of the bone marrow, together with the fact that radioactivity disappears gradually and dosage can be adequately controlled, indicate that this method of treatment is superior to other methods employed in the past. Complications such as leukemia may be produced, and adequate observation is essential in order to prevent severe damage to the bone marrow.

At present it may be concluded that there is adequate evidence to accept the palliative effect of radioactive phosphorus in leukemia and some allied disorders; whether more than palliative effect can be obtained by subsequent investigations into dosages and other technics of administration must be considered doubtful. Although radioactive phosphorus does not bring about a complete cure for polycythemia vera, it can produce a long-lasting remission of the clinical and hematologic manifestations. When the exigencies of the war are past, an adequate supply of radioactive phosphorus probably will be available; the preparation, however, must be administered with great care and circumspection. Its careless use can bring about disorders as serious as those which it is designed to relieve.

PHYSICIANS AND ADOPTIONS OF BABIES

In pioneer days the family physician was naturally the person with whom to discuss the adoption of a baby. He knew the unwanted babies. He was expected to maintain secrecy and to respect confidences. For many years the informal adoptions arranged by physicians were as satisfactory a way as could be found. Physicians have continued to function in this capacity. Here and there abuses have been observed, but the vast majority of physicians, in arranging adoptions, do so without profit to themselves and with a view only to the advantage of the baby, the real parents and the foster parents. Many nonmedical abuses have crept into the field of adoption. "Baby farms" and disreputable foster homes, in which unwanted babies were left and from which they are taken by foster parents, often profit both ways from such transactions; they charge mothers for "care" of the baby, often at prohibitive rates; they charge the foster parents all that the traffic can bear.

The control of illicit traffic in babies requires that all adoptions should be a matter of public concern. The state, in taking control, has developed certain general principles which have been republicized by the United States Children's Bureau.[1] Press releases include a comprehensive description of a desirable adoption law covering many points. The general principles which should govern adoption are set forth by the bureau as follows:

1. Adoption proceedings should be held before a local court accustomed to handling children's cases; petitioners for adoption should reside and be known locally.
2. The court should have the assistance of the state welfare department, which should be made a party to every adoption proceeding.
3. Consent to adoption should be obtained from natural parents or other persons or agency having legal responsibility.
4. Court hearings should be closed and records confidential.
5. A trial period of residence, preferably for one year in the adopted home, should be required prior to issuance of the final adoption decree.
6. Provision for removal of children from unsuitable homes should be made as well as provision for their care and guardianship after such removal.
7. All applicable statutes should assure the welfare of the child and the rights and obligations of the parents.

The children of unmarried mothers are particularly subject to possible abuses because of the desire to conceal the illegitimate birth, the emotional state of the mother at the time of birth and the consequent tendency to act rashly in a manner which will be regretted later.

The Children's Bureau declares [1] that not more than one fourth of the states have adoption laws which approximate the standards set forth, although within the last five years about forty states have improved their legislation in some respects.

In view of the increasing complexity of legal and sociologic implications involved in adoption state laws may eventually establish specialized agencies to supervise the adoption of children and the physician's role in that field will be restricted. Much of the abuse now present in the field can be minimized by the enactment and enforcement of adequate laws respecting child placement agencies.

"PSEUDODOXIA PEDIATRICA"

Under the heading "pseudodoxia pediatrica" Bakwin [1] calls attention to a number of doubtful practices in current use among pediatricians. The worst offender among these, he believes, is indiscriminate tonsillectomy. The American Child Health Association, some ten years ago, surveyed a group of 1,000 children 11 years of age from the public schools of New York City; 61 per cent had had their tonsils removed. The remaining 39 per cent were subjected to examination by a group of physicians who, in turn, selected 45 per cent of these for tonsillectomy and rejected the rest. The rejected children were reexamined by another group of physicians, who recommended for tonsillectomy 46 per cent of those remaining after the first examination. When the rejected children were examined a third time, a similar percentage was selected for tonsillectomy, so that after three examinations only 65 children remained who had not been recommended for the operation. Apparently the chance that a child would be recommended for operation depended principally on the physician rather than on the status of the child's health. In groups of children with severe dental caries and visual handicaps for which nothing had been done, about 60 per cent were submitted to tonsillectomy. Another operation often performed without sufficiently specific indications is myringotomy. The author showed at Bellevue Hospital, before the use of sulfonamide drugs, that the incidence of purulent otitis media in infants could be greatly reduced by limiting otoscopic examinations and adhering to stringent criteria for myringotomy.

We are rather proud of our record of deliveries of mothers in hospitals in the United States. Bakwin reminds us, however, that data are not available to prove that indiscriminate hospitalization for delivery has had a favorable influence on either maternal or neonatal mortality. There is material for thought in the report of the Frontier Nursing Service of Kentucky.

1. Bakwin, Harry: Pseudodoxia Pediatrica, New England J. Med. 232: 691 (June 14) 1945.

The service has reported a maternal mortality of 0.75 per thousand births in its first 4,000 deliveries, as compared with 5.6 for the white population of the United States of the same time. These deliveries were done in homes which were extremely poor. Operative deliveries were rare, and stillbirth and neonatal death rates did not differ significantly from those of the country as a whole.

Bakwin believes that hospitals are unsuited for the care of the newborn. The obstetric nurseries are crowded and expose the infants to epidemics, particularly those of diarrhea. Pneumonia, sepsis and other infections are not infrequent. These conditions are rare in the home. Recent studies suggest that the separation of mother and baby, as practiced in hospitals, is unnatural and unphysiologic. The system of bringing babies to their mothers only at fixed intervals and allowing them to remain for limited periods, he argues, is not conducive to proper breast feeding, especially during the first three weeks of life. Bakwin readily agrees that the hospital is the proper place for the delivery of selected patients when difficulties are anticipated, but he feels that some modification of the present system of indiscriminate delivery in hospitals should be made.

Among many fallacies resulting principally from rationalization without scientific check, those pertaining to the field of nutrition offer a fruitful field. Infants are fed vitamins, although there is not definite clinical evidence that deficiency diseases are common among children or that any benefit can be derived from the general use of vitamins except in the case of vitamins C and D in infancy. The major fallacy, Bakwin points out, is to think that the appetite cannot be trusted in the selection of a proper diet and that laboratory investigations have progressed to the stage where they can be trusted to make such a selection. He insists that eating should mean roasts, sauces, puddings or pies rather than calories, vitamins and minerals, and that if he was to choose between chef and dietitian he would choose the chef.

Explanation for the continuation of these practices, according to Bakwin, is the tendency to accept ideas rather than to question them and subject them to experiment and clinical control. The indifference of the academic pediatrician to the details of everyday practice, the type of training given to the future pediatrician and his orientation toward his practice are all factors. The physician often feels that he must do something; in his anxiety to act he frequently does too much to the detriment of both the child and the parent.

The iconoclast is not new in medical science. The continuous questioning of its own theories and practices is conspicuous in modern medicine. Iconoclasm serves a useful purpose. Let us remember that often the results serve to restore new faith in old methods, by placing them on firmer foundations.

Current Comment

THE ANTIRETICULAR CYTOTOXIC SERUM OF BOGOMOLETS IN THE TREATMENT OF RHEUMATISM

The therapeutic agent called the antireticular cytotoxic serum of Bogomolets (A C S) is based on the concept that the connective tissue of an organism contains a number of hitherto uninvestigated physiologic functions. The aim of the serum is to stimulate these functions and to intensify active immunity. The serum is produced by the immunization of horses with the cells of the spleen and bone marrow taken from a human corpse. The determination of the amount of cytotoxins in the serum obtained is important. The amount of cytotoxins in the serum of the immunized animal can be determined by applying a modification of the reaction of complement fixation (reaction of Bordet-Gengou); that is, by using an antigen for the reaction of complement fixation, the same antigen as is used for the immunization of the animal. The strength of the serum is determined by ascertaining the dilutions at which it still gives a complete fixation of the complement. Therapeutic serums are those which give a complement fixation in a dilution of not less than 1 : 100. The serum is injected subcutaneously in an isotonic solution in the dilution of 1 : 10. The stimulating dose of the diluted serum equals 0.3-1.0 cc. Small doses of cytotoxic serum have a stimulating effect; whereas large doses have an inhibitory effect. The reactivity of the physiologic system of connective tissue can be determined, according to Bogomolets, by a number of tests such as the dermal tests with trypan blue, blood morphology, the sedimentation speed of erythrocytes, the titer of the complement, the opsonic index and the phagocytic activity of the leukocytes. Among the numerous conditions in which the serum is supposed to exert a favorable effect is "rheumatism." In a report to the Empire Rheumatism Council on the action of this serum in 48 selected patients representing various types of "rheumatism," Francis Bach [1] states that his investigation does not support the claim that the antireticular cytotoxic serum of Bogomolets is a cure for "rheumatism." Definite subjective improvement was observed in only 7 of this group, while in another 7 there was slight improvement. Of the 3 cases of rheumatoid arthritis which showed definite improvement, there was a relapse two months later. Bach suggests that the type of the case and the stage in the pathologic process that has been used for this preliminary study are probably not those which Professor Bogomolets had in mind. In fact, when asked for an opinion regarding this report, Bogomolets stated that he has come to believe that his serum is suitable only in the acute phase of the rheumatic disease. Professor Strozhesko, one of Russia's prominent internists, in whose clinic the action of the serum in rheu-

1. Bach, Francis: A. C. S. Serum of Professor Bogomolets in the Treatment of Rheumatism, Ann. Rheumat. Dis. 4: 62 (March) 1945.

matism was studied, stated that the serum in stimulating doses produces the best effect with infectious diseases in what he calls the allergic period of their course. The efficiency of this serum in rheumatic conditions is at least doubtful. The burden of proof is still on the proponents.

THE GIBSON ISLAND CONFERENCES ON CHEMISTRY

The special research conferences on chemistry and its allied fields, held at Gibson Island under the auspices of the American Association for the Advancement of Science, are now in session. The recent conference on medicinal chemistry bore testimony to the current interest in antibiotics and their role in chemotherapy. Prospects for several competitors or collaborators with penicillin are encouraging. That the chemists have not abandoned the search for symptomatic remedies, however, was borne out by the interest shown in new analgesics, antispasmodics and antithyroid compounds. In the case of the chemotherapeutic agents as well as of the pharmacodynamic agents, great interest attaches to the relation of chemical structure to biologic activity. As was repeatedly brought out in the discussions, such relationships are important in directing the synthesis of new compounds but have a limited predictive value as to the merits of a new compound synthesized to specifications. As the testing and appraisal of new drugs is often more arduous and time consuming than their preparation there is a virtual log jam of new compounds awaiting tests and appraisal. Abbreviated "screening methods" are necessarily employed but could not be expected to be wholly satisfactory.

MEDICAL BOOK REVIEWS

The quality of reviews of books in the field of medicine in five representative medical journals has recently been evaluated.[1] The criteria by which the contents of the reviews were judged were discussion of author's qualifications and basis of his work; indication of whether the book is a reference book, textbook or manual; indication of the author's purpose in writing the book, his objectives and point of view; inclusion of subject matter covered, as well as scope of book; format, type, illustrations, plates and bibliographies; indication of manner of treatment, style of writing and effectiveness; indication of the accuracy of the author's statements, and inclusion of comparison with related books in the field or similar books by the same author. By rating the five journals from 0 to 5 on these criteria, it was found that THE JOURNAL, with an average of three or better on four different points, namely, purpose, subject, reliability and form, obtained the highest rating of the five periodicals with a total average score of 2.5. This study and its conclusions furnishes objective evidence of the reliability and value of the reviews published in THE JOURNAL.

INTELLIGENCE AND SEX

There is no difference in mean intelligence between boys and girls. This fact has been shown repeatedly by adequate studies of performance of boys and girls when subjected to modern methods of intelligence testing. There is, however, a real, i. e. statistically valid, difference in the degree of variance of intelligence between boys and girls. There are more boys at both extremes of intelligence—brighter and duller—than there are girls. Roberts,[1] in a thoughtful discussion of this subject, states that in the one thousand "cleverest" or "dullest" children out of ten thousand there are 534 boys to 466 girls, or a ratio of 115 boys to 100 girls. This variance increases as one approaches the extremes of intelligence. Thus in the final 0.1 per cent at the highest and lowest intelligence levels there are nearly twice as many boys as girls. That boys are so much more variable than girls in regard to general intelligence is one of the most curious facts in human biology, especially in view of the lack of difference in mean performance. There is no doubt as to the reality of the phenomenon. Roberts, probably correctly, eliminates any differential cause due to education during school or preschool life and concludes that the difference is almost certainly genetic, but in what manner this is brought about is at present completely obscured.

MORE HOME CANNING

Every indication points to the need for matching again this year the record set for home canning during 1944, when nearly one half of the total canned vegetables and two thirds of the canned fruits used by civilians were home canned. The War Food Administration has prepared numerous suggestions on means of disseminating information for the promotion of home canning. These include the use of radio, clubs, schools, churches and demonstration centers to interest the housewife in food preservation and to assist her in every way possible. The problems of home canning this year are further complicated by the necessary cut in the allotment of sugar for this purpose. This obstacle can be overcome in part by the use of numerous methods of preservation which require little or no sugar. Fruits may be kept from spoiling by processing without sugar or by substituting part corn syrup or honey. The drying of fruits in home built dehydrators does not require sugar. More pressure cookers are available this year, without priority, through regular commercial channels, for efficient canning of vegetables other than tomatoes. Instructions for the use of these canning procedures and equipment are provided in the many publications of the Department of Agriculture and the War Food Administration. The campaign to acquaint the public with the need for more canning and better canning is much to the point in view of the nation's food situation.

MEDICINE AND THE WAR

ARMY

56th PORTABLE SURGICAL HOSPITAL

The 56th Portable Surgical Hospital was recently recognized for superior and meritorious service while attached to the veteran 33d Infantry Division during the rugged fighting in the Benguet Mountains of northern Luzon. Commanded by Major Evan C. Reese of Stroudsburg, Pa., the 56th Portable Surgical Hospital was awarded the Meritorious Service Unit Plaque by Major Gen. P. W. Clarkson, commanding the 33d (Prairie) Division, which liberated Baguio. The citation stated that "the excellent care given patients has resulted in the saving of many lives and in returning many casualties to a full duty status. The 56th Portable Surgical Hospital achieved and maintained a high standard of military discipline throughout the entire Baguio campaign."

FIRST MEDICAL OFFICER TO BE DISCHARGED UNDER POINT SYSTEM

The Office of the Surgeon General stated recently that Major Wallace P. Ritchie, St. Paul, will be the first medical officer to leave the Army under the point discharge system. He has 121 points, having served thirty-three months overseas in England, North Africa and Italy. Dr. Ritchie graduated from Johns Hopkins University School of Medicine, Baltimore, in 1931 and entered the service Feb. 15, 1942.

GENERAL BURSTON OF AUSTRALIA IN THE UNITED STATES

Major Gen. S. Roy Burston, Director General of Medical Services of the Australian Military Force, was in Washington recently, where he conferred at the Office of the Surgeon General. He arrived in this country on an inspection trip during which he will visit military medical installations and medical foundations in the United States and Canada.

ARMY AWARDS AND COMMENDATIONS

Captain Herman Schneck

Capt. Herman Schneck, formerly of New York, was recently commended "for superior performance of duty and maintenance of medical facilities." The commendation read, in part, "You have imbued all members of this command with profound confidence in your ability, by skilful and efficient treatment of the many and varied cases that have developed here, and we all feel that we are indeed fortunate to be in such good hands. Recently pictures have been taken of the post dispensary and war building by photographers dispatched from department headquarters, with the intention of publishing them as models. . . . The undersigned is well aware of the poor facilities that existed at this post prior to your arrival, and it is desired that you receive full credit for the present condition of the medical facilities of this post, which have been so well liked by our superior headquarters and have caused this signal honor to be conferred on our command." Dr. Schneck graduated from the New York University College of Medicine, New York, in 1917 and entered the service Dec. 3, 1942.

Major Homer W. Humiston

Major Homer W. Humiston, formerly of Tacoma, Wash., was recently presented with the Bronze Star, accompanied by a citation "for meritorious service in connection with military operations against the enemy on Leyte, P. I., from Nov. 24 to Dec. 25, 1944. As assistant chief of the surgical service Major Humiston rendered a type of surgery to wounded soldiers and civilians that was outstanding. In addition to spending long hours in the surgery, he supervised the preoperative and serious postoperative wards in a manner that was worthy of merit. By his skill as a surgeon plus his devotion to the patients, Major Humiston saved the lives of many men as well as hastening the recovery of others less seriously injured." Dr. Humiston graduated from Harvard Medical School, Boston, in 1925 and entered the service Nov. 5, 1942.

Major Hildrus A. Poindexter

The Bronze Star was recently awarded to Major Hildrus A. Poindexter, formerly of Washington, D. C., "for meritorious service in support of military operations against the enemy at an island base in the Southwest Pacific Area. During the period of June 15, 1944 to Oct. 30, 1944 Major Poindexter not only acted in the capacity of an infantry division malariologist but also performed the additional duties of an island command malariologist. By his faithful, energetic, aggressive and skilful work on the problems of malaria control, the rate of malaria fever among members of the command was materially reduced Major Poindexter's services reflect credit on himself and on the military service." Dr. Poindexter graduated from Harvard Medical School, Boston, in 1929 and entered the service April 22, 1943.

Lieutenant Colonel Eugene F. Melaville

Lieut Col. Eugene F. Melaville, formerly of Rochester, N. Y., was recently awarded the Bronze Star for "meritorious achievement in connection with military operations against the enemy on Peleliu Island, Palau Group, from Oct. 4 to Nov. 27, 1944. In the absence of normal third echelon medical service, the facilities of the division clearing company and a portable surgical unit were combined to hospitalize wounded and sick of the division and attached units. . . . By his untiring effort and vigilant supervision, Colonel Melaville made a splendid contribution to the efficient hospitalization furnished the division in the Palau Islands." Dr. Melaville graduated from Washington University School of Medicine, St. Louis, in 1938 and entered the service July 1, 1942.

Captain Robert S. Hormell

In recognition of his "outstanding conduct in the performance of duty," Capt. Robert S. Hormell, formerly of Boston, was recently commended by Major Gen. R. G. Breene, U. S. Army, the citation reading that Captain Hormell, "by denying himself sleep and rest did, during the month of April, save the life of a colored soldier who was severely burned and injured in a gasoline explosion on April 4, 1943. For the first forty-eight hours following this accident this officer remained constantly at the side of the injured soldier, and as a result of his personal knowledge and skill and through his perseverance when the rest of the staff despaired of this soldier's life, the soldier's life was saved." Dr. Hormell graduated from Harvard Medical School, Boston, in 1939 and entered the service June 1, 1942.

Major Thomas R. White

A Distinguished Flying Cross was recently awarded to Major Thomas R. White, formerly of Redlands, Calif., for "extraordinary achievement while participating in a highly destructive raid on the Japanese mainland on April 18, 1942. These officers and enlisted men volunteered for this mission knowing full well that the chances of survival were extremely remote and executed their part in it with great skill and daring. This achievement reflects high credit on them and on the military service." Dr. White was also awarded the Silver Star and the Military Order of China. Dr. White graduated from Harvard Medical School, Boston, in 1937 and entered the service Aug. 15, 1941.

NAVY

PHYSICAL REQUIREMENTS FOR DUTY ABOARD SUBMARINE

Lieut. Comdr. J. J. Blanch, senior medical officer aboard a submarine tender in the Pacific, recently outlined the rigid physical requirements for duty aboard a submarine, as follows: The submarine man should be lean and agile so as not to take up too much space aboard the subs, which are very cramped for space. A slender person can also get around much easier. He must have 20/20 uncorrected vision and be able to hear a standard navy clock at 40 inches. He must not be afflicted with chronic throat trouble, nor must he have a fungous infection allergy. The sub man must meet special dental requirements, since there is no way of rendering dental aid while on patrol. A man suffering from claustrophobia does not qualify. A near-perfect physical specimen, who is cool and not easily perturbed during an emergency, is the type of man for the submarine service. Since the crew on a submarine is comparatively small, every man must be physically able to perform his job well under all circumstances. When submarines return to a tender following a patrol, the crew, after being examined physically, are sent to a rest camp for two weeks, during which time an emergency crew aboard the tender prepares the boat for action again.

NAVY AWARDS AND COMMENDATIONS

Commodore John Paul Owen

The Legion of Merit was recently awarded to Commodore John Paul Owen, formerly of Oak Grove, Mo., who was cited "for exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as medical officer in command of the Naval Hospital, Navy Yard, Mare Island, Calif., from Nov. 11, 1942 to March 1, 1945. Exercising sound judgment and outstanding technical ability, Commodore Owen rendered valiant service in carrying out the varied and complex details of his vital assignment, laboring tirelessly and with unceasing diligence in expanding his hospital to meet the demands of ever growing lists of casualties returned from battle fronts all over the world. In addition to his administrative duties at the hospital, he undertook the development of a plastic artificial limb which has been extensively recognized in medical and scientific fields and universally adopted as an orthopedic device of inestimable value in rehabilitating wounded men of all Allied Nations, supervising the manufacture of the new device on the premises. By his superior knowledge, expert professional skill and zealous devotion to this extremely vital task, Commodore Owen served as a constant inspiration to the returning veteran in resuming his normal place in society." Dr. Owen graduated from St. Louis University School of Medicine in 1913 and entered the service April 14, 1917.

Lieutenant Jack C. McCurdy

Lieut. Jack C. McCurdy, formerly of Marshall, Texas, was recently presented with the Navy Unit Commendation Ribbon for the First Provisional Marine Brigade in recent ceremonies at the Naval Air Station, Pensacola, Fla. He is now attending the School of Aviation Medicine in Pensacola preparatory to receiving the wings of a flight surgeon. Already the holder of a Navy Cross and the Purple Heart, Dr. McCurdy was attached to the First Provisional Marine Brigade for one year and was with it during the assault on Guam. It was during that period, from July 21 to Aug. 10, 1944, that the brigade won the Navy Unit Commendation. He won the Navy Cross for his action during the first day of the assault on Guam while he was attached to a Marine battalion. He was also wounded during the Guam battle. Dr. McCurdy graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1941 and entered the service Jan. 5, 1942.

MISCELLANEOUS

QUINACRINE HYDROCHLORIDE (ATABRINE) FOR CIVILIANS

The War Production Board recently announced that the military services have stated that a small percentage of veterans now being discharged from the services will require some form of antimalarial treatment during periods of relapse of this disease. Quinacrine hydrochloride (atabrine) is readily available in adequate supply to meet civilian requests for both oral and parenteral use, according to the War Production Board. Quinine may be obtained in ampule form for parenteral use when required, but it is not available for oral use. However, totaquine U. S. P., representing the total alkaloids of cinchona bark, is available for oral use in quantities sufficient to meet all requests for natural antimalarials.

Physicians and patients who require such medication should purchase their supplies from local druggists or other sources of pharmaceutical products. Occasionally local druggists, particularly those in the Northern sections of the country, may not have stocks of quinine ampules, totaquine or quinacrine hydrochloride (atabrine) on hand. Under such circumstances the druggists should be requested to obtain the desired items from wholesalers or from the manufacturers of these products, through their usual channels of distribution.

PHYSICIANS WITH THE VETERANS ADMINISTRATION

At the suggestion of the Secretary of War, the Administrator of Veterans Affairs has agreed that the Readjustment Regulations will be applicable to Medical Corps officers assigned to the Veterans Administration. When the critical adjusted service rating score has been formally announced, officers who are assigned to the Veterans Administration may be relieved from active duty the same as officers who are serving with the Army under these regulations. Attention is also called to the fact that any Medical Corps officer assigned to the Veterans Administration has the privilege to request relief from active duty under the provisions of section III or IV, War Department Circular 485, dated Dec. 29, 1944. If an officer submits a request for relief from active duty under section III, he must accompany his request with a statement from the executive officer, Procurement and Assignment Service, War Manpower Commission, showing the need for his services in a community.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, July 21, page 887)

CONNECTICUT

Norwich State Hospital, *Norwich.* Capacity, 2,600; admissions, 737. Dr. Riley H. Guthrie, Superintendent (4 residents—psychiatry, 3 disqualified for military service).

Waterbury Hospital, Waterbury. Capacity, 372; admissions, 8,402. Miss Aida E. Creer, R.N., Superintendent (interns, April and July; resident, April).

KENTUCKY

Louisville General Hospital, Louisville. Capacity, 587; admissions, 9,971. Dr. John W. Moore, Medical Director (assistant resident—pediatrics, disqualified for military service).

MASSACHUSETTS

Cambridge Hospital, Cambridge. Capacity, 272; admissions, 6,078. Dr. F. A. Washburn, Medical Director (interns; assistant resident, discharged medical officer).

NEW YORK

Goldwater Memorial Hospital, New York City. Capacity, 1,660; admissions, 1,676. Dr. C. G. Scherf, Medical Superintendent (resident).

Metropolitan Hospital, New York City. Capacity, 1,183; admissions, 8,838. Dr. Randolph A. Wyman, Medical Superintendent (interns, October 1).

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

July 23, 1945.

A National Science Foundation

Legislation embodying the Kilgore subcommittee recommendation for creation of a national science foundation to oversee research of government agencies, industries and private organizations will be introduced this week by Senators Kilgore of West Virginia, Johnson of Colorado and Pepper of Florida. A bill already drawn by the subcommittee on war mobilization provides for a $15,000 a year director and a seventeen member national defense board, including the heads of the War, Navy, Interior, Agriculture, Commerce, Labor and Justice departments and the Federal Security agencies. The Kilgore proposal, following issuance of the Bush report, which advocated a nine member board, would create a foundation to distribute federal funds for research in the weapons of war, health and medical care, advancement of the basic sciences and other activities. Under the Kilgore plan, funds would be allocated as follows: Twenty per cent of an annual appropriation, total to be determined by Congress from year to year, appropriated annually to each of three main branches: national defense, health and medical care, and basic sciences. Funds would also be allocated to research on natural resources, methods, products and processes of value to small business, and on peacetime uses for wartime research and wartime facilities. At least 50 per cent of each year's funds would be earmarked for nonprofit educational institutions and research foundations. They would be "free to conduct their research work in a manner which they think most productive, subject only to routine supervision and review by the foundation."

Better Artificial Limbs Requested for Servicemen

More intensive research on the development of better artificial limbs for servicemen was urged by Representative Rogers of Massachusetts in the House. She said that they are not getting the best artificial limbs that science could devise. Ranking minority member of the House Veterans Committee, long interested in medical legislation, Mrs. Rogers did not blame the Army entirely for failure to provide better appliances for veterans but said that the War Department had ample funds to do more than has been done. She commended the project started under the direction of Gen. Brehon B. Somervell, commanding general of the Army Service Forces. Mrs. Rogers reported conversations with amputees at Walter Reed Hospital who said that their artificial limbs were none too comfortable or practical. Representative Miller of Nebraska, a physician, agreed with Mrs. Rogers that the army amputee center was not making entirely satisfactory artificial limbs.

Research Laboratories Studying Better Artificial Limbs

Coincident with criticism by House members of artificial limbs now supplied to servicemen were reports of how research is being pressed in laboratories of General Motors, Northrop Aircraft and other war plants in an effort to make better artificial arms and legs. It is reported that some of the new technics and materials used in the production of airplanes will be used to help provide wounded soldiers and sailors with the best artificial limbs. A belated effort is now said to be under way to solve the problem that Dr. Paul E. Klopsteg of Northwestern University, head of the research program set up by the government's Office of Scientific Research and Development, said "should have had attention years ago." It is claimed here that the government did nothing until a few months ago because the artificial limb industry, which is soon to be investigated by a federal grand jury, had strongly opposed suggestions that the government foster such research. It took some effort to convince high government officials that the research was necessary, it is stated. The American Legion has charged that "the manufacturers have neither the resources nor the equipment to engage in extensive research engineering unless government agencies assist." To this charge, which was forwarded to Brig. Gen. Frank T. Hines, former head of the Veterans Administration, Chester O. Hadden of Denver, official of the Gaines Artificial Appliances firm and president of the Association of Artificial Limb Manufacturers of America, is reported to have replied that the legion resolution was not based on fact. He said that members of the industry spend "many thousands of dollars year after year" in research and that "there is absolutely no necessity for the allocation of any federal funds for research in this field at the present time."

A Broad Program of Scientific Research

Better health, more jobs in peacetime and the development of new weapons of war are objectives of a broad scale, publicly financed program of scientific research, urged by Dr. Vannevar Bush, director of the Office of Scientific Research and Development, in a report to President Truman. Representative Jennings Randolph and Senator Warren R. Magnuson have proposed a bill to implement the Bush report. The report recommends that Congress establish a National Research Foundation with five divisions to study specific fields of study. An initial $35,000,000 program is urged, with costs to rise as work increases, to finance research and provide 24,000 undergraduate scholarships and 900 graduate fellowships to augment the roll of scientists. The Bush report is based on the findings of four committees of specialists, drafted in response to a request to him by the late President on Nov. 17, 1944. Three specific recommendations in Dr. Bush's report are that the foundation be formed to develop scientific research, financially support basic research in nonprofit organizations, encourage scientific talent in American youth by offering scholarships and fellowships and promote long range research on military matters; that the foundation consist of nine members to be elected by the President and be responsible to him, to serve four years and without compensation, and that the foundation have five divisions: medical research, natural sciences, national defense, scientific personnel and education, and publications and scientific collaboration. In urging government support of scientific research, Dr. Bush said that at present there are forty separate agencies in the government carrying on various forms of scientific work. Since 1930, he said, funds spent by the government and by industry for scientific research had increased from $140,000,000 to $309,000,000 in 1940. In the same period colleges and universities raised their expenditures from $20,000,000 to $31,000,000, while money spent by research institutes dropped from $5,200,000 to $4,500,000.

Women Physicians to Have Important Postwar Role

Women physicians, who before the war constituted less than 5 per cent of the 165,000 physicians practicing in the United States, will have a larger part in filling postwar medical needs, according to the Women's Bureau of the Department of Labor. A bureau report said that the war has greatly increased the demand for women physicians, both for the army and navy and to replace doctors who have gone into the armed forces. Only four out of the seventy-seven approved medical schools in this country now refuse admission to women. While women have tended to specialize in pediatrics, psychiatry and public health, it is expected that they will expand into other medical fields, including medical research and teaching, after the war.

U. S. Navy Studies New Age-Service Discharge Plan

The U. S. Navy is considering a new, age-service point system under which older reserve officers and enlisted men will be discharged or released to inactive duty. An estimated 11,600 officers and 19,000 enlisted men would be eligible for return to civilian life under the system by next December. The minimum points required range from 53 to 57, depending on the service branch, and the new plan calls for computing a man's "service age" by allowing one point for each year of age, plus an additional point for each four months of active duty since September 1 when Germany invaded Poland.

Bureau of Information

SUMMARY SHEETS FORM INDIANA AND PENNSYLVANIA

Completed county summary sheets have been received from each county in Indiana through Mr. Thomas Hendricks, secretary of the Indiana State Medical Society, and from each county in Pennsylvania through Dr. Walter F Donaldson, secretary of the Medical Society of the State of Pennsylvania.

Pennsylvania

1 Bureau of Census, estimated population 1943
2 Bureau of Census, population 1940
3 Based on 1940 figures, American Telephone and Telegraph Company.

The accompanying table gives data from selected counties in each of these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities They are not included in computing physician population ratio, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities

Medical Legislation

MEDICAL BILLS IN CONGRESS

Scientific Research

Three bills have been introduced to promote the progress of science and the useful arts, to secure the national defense and to advance the national health, prosperity and welfare, S. 1285, introduced by Senator Magnuson, Washington, H. R. 3852, introduced by Representative Mills, Arkansas, and H. R. 3860, introduced by Representative Randolph, West Virginia. These bills undertake to effectuate the recommendations of the report submitted recently to President Truman by Dr. Vannevar Bush and other scientists who were requested by former President Roosevelt to suggest what the federal government should do to foster scientific research.

This legislation proposes to create a National Research Foundation to be composed of five divisions, including a Division of Medical Research. The foundation will be directed (*a*) to develop and promote a national policy for scientific research and scientific education; (*b*) to initiate and support basic scientific research and scientific development in the mathematical, physical and biologic sciences through contracts, grants or other forms of assistance; (*c*) to initiate and support scientific research and scientific development on matters relating to the national defense through contracts, grants or other forms of assistance; (*d*) to discover and develop scientific talent, particularly in American youth; (*e*) to grant scholarships and fellowships in the mathematical, physical and biologic sciences; (*f*) to foster the interchange of scientific information among scientists in this country and abroad; and (*g*) to correlate the foundation's scientific research and scientific development programs with those undertaken by public and private research groups.

The legislation would authorize to be appropriated annually such sums as may be necessary to carry out its provisions.

Industrial Health Hazards

Senator Johnston, South Carolina, for himself and Senator Ball, Minnesota, has introduced S. 1271, to provide for cooperation with state agencies administering labor laws and establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation and enforcement of regulations to control industrial health hazards. This bill is identical with the one introduced in the House of Representatives by Representative Norton, New Jersey, which is pending on the House calendar with a favorable committee report.

Official Notes

THERAPEUTIC TRIALS COMMITTEE

In the published statement of the October 1944 annual meeting of the Council on Pharmacy and Chemistry (THE JOURNAL, May 5, p. 29) announcement was made concerning the establishment of a Therapeutic Trials Committee. This committee has met in session on several occasions and on July 17 met with representatives of the American Drug Manufacturers Association and American Pharmaceutical Manufacturers Association to discuss procedure. In due time a formal announcement of the functions of this committee and the procedure by which it will serve will be published in THE JOURNAL.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

"Food Faddist" Arrested.—Paul O. Sampson, alleged food faddist, was arrested recently and booked at the Chico City Jail on four charges of violating the medical laws and the pure food laws of California. He was held in $2,000 bail and was finally released on personal recognizance to his attorney. Sampson was charged with violating the medical laws business and professional code for practicing a system of treating the sick without a license, newspapers reported.

Clair Turner Joins University of California.—Clair E. Turner, Dr.P.H., temporarily on leave from the Office of the Coordinator of Inter-American Affairs as health education officer, has been named in charge of the public health education program in the University of California School of Public Health, Berkeley, according to the University *Clip Sheet*. He will have the title of visiting professor of public health education. The course will be graduate in nature and will lead to the degree of master of public health.

Abortion Activities.—Newspapers reported June 12 the arraignment of Hester Ann Hesketh on a charge of murder in connection with the death of a young woman. It was stated that Mrs. Hesketh had admitted that she had performed from thirty to thirty-five abortions a week for the past two years and admitted too that she had been carrying on this activity since arriving in the state eighteen years ago. Her fees ranged from $25 to $75.——Clyde A. Pierson, D.O., San Bernardino, on May 25 was held legally convicted of abortion by the California fourth district court of appeals but the sentence to a prison term was cut in half, newspapers reported May 25. According to the opinion of a superior court judge, Pierson would have to serve one term of from two to five years and then serve a second term for the second and third counts combined, for which he was found guilty more than a year ago, it was stated. The appellate court decision stipulates that the conviction on two of the counts was not according to law. Pierson now has one conviction against him and must therefore serve one term. It was stated that this single conviction will be carried to the supreme court.——A chiropractor, Ramon S. Davis, on May 25 was being held by authorities in Los Angeles County for allegedly performing an illegal operation. Arresting authorities said that the chiropractor admitted performing the operation in a full confession, it was stated.

CONNECTICUT

Personal.—Dr. Creighton Barker, New Haven, secretary of the Connecticut State Medical Society, has been appointed a member of the board of trustees of the University of Connecticut, Storrs.——Joseph S. Fruton, Ph.D., associate in chemistry at the Rockefeller Institute for Medical Research, New York, has been appointed associate professor of physiologic chemistry at Yale University, effective July 1

Display Honors Dr. Winslow.—The Yale Medical Library has arranged a special exhibit in recognition of the services of Charles-Edward A. Winslow, Dr.P.H., senior member of the faculty of the Yale University School of Medicine, who was to retire in his position as professor of public health at the end of the recent school year (THE JOURNAL, March 31, p. 865). The exhibit includes early writings on hygiene beginning with Galen and a copy of the rare first edition of Sir John Harington's "Metamorphosis of Ajax," which described his invention of the water closet. Five display cases are devoted to Dr. Winslow's own writings.

DISTRICT OF COLUMBIA

Georgetown Opens Campaign for Funds.—Georgetown University Hospital has launched a campaign for funds to build a new institution. The campaign goal is $750,000, the same sum needed to supplement and guarantee a federal grant of $1,820,000 provided under the Lanham act for construction of the new building. The proposed hospital is to have 400 beds and will be erected adjacent to the university medical and dental schools. The new building will replace the old Georgetown University Hospital, which has a capacity of 241 beds and which was erected in 1898.

FLORIDA

Personal.—Dr. Hubert A. Barge, Miami, has been awarded the Algernon Sydney Sullivan medal of Mercer University, Macon, Ga. The medal is given annually to the most prominent alumnus of the school. According to the Jacksonville *Times-Union*, Dr. Barge, who graduated in 1918 at the school, has been instrumental in obtaining buildings and endowments valued at more than five million dollars to the university since 1934.——Dr. John S. McEwan, Orlando, has been appointed a member of the Florida Crippled Children's Commission to succeed Dr. Sanford C. Colley, Mount Dora, whose term expired.

ILLINOIS

Hospital Survey.—Governor Dwight Green has designated and authorized the state department of public health to carry on a survey of hospital facilities in the state of Illinois. Six persons representing the hospital field are to be appointed shortly by the governor and will be included in the overall advisory committee, which will consist of about forty members representative of labor and various civic organizations. A small technical subcommittee will be made up of hospital representatives and physicians. The development of the project is credited to the council on government relations of the Illinois Hospital Association.

Tumor Diagnostic Clinic Established.—A tumor diagnostic service has been organized at the Christian Welfare Hospital in East St. Louis to be conducted under the auspices of the state department of public health through its division of cancer control. The unit will provide a consultation service for practicing physicians of the area in the care of their suspected tumor cases. Similar services are now functioning under the auspices of the state department of health at the Memorial Hospital, Springfield; Burnham City Hospital, Champaign; St. Anthony's Hospital, Rockford, and the Research and Educational Hospitals of the University of Illinois College of Medicine at Chicago.

Ringworm of the Scalp Must Be Reported.—Dr. Roland R. Cross, director of the state department of public health, has announced that effective July 10 all cases of ringworm of the scalp occurring in Illinois must be reported to the official public health authority having local jurisdiction. Children infected with the disease shall be excluded from schools, theaters and public places until all lesions have healed. Placarding of homes and complete isolation will not be required, but disinfection of all towels, washcloths and head coverings of all articles used by patients will be enforced. All persons under 15 years of age that have been in contact with the patients should be inspected for evidence of the infection.

Chicago

Special Society Elections.—New officers of the Chicago Society of Allergy include Drs. John Peters, Oak Park, president, William A. Mowry, Madison, Wis., president-elect and Edward G. Tatge, Evanston, secretary-treasurer.——Drs. J. Daniel Willems was chosen president of the Chicago Society of Industrial Medicine and Surgery, Karl G. Rundstrom vice president and Frank P. Hammond secretary-treasurer.

Lectures on Health.—Dr. Harry M. Hedge, assistant professor of dermatology, Northwestern University Medical School, gave the first lecture July 18 in a summer lecture series given at the Museum of Science and Industry with the museum, the Chicago Medical Society and the Illinois State Medical Society cooperating. His subject was "Care of the Skin and Cosmetics." Dr. Chauncey C. Maher, associate professor of medicine, Northwestern, gave the second lecture July 25 on "High Blood Pressure." Others in the series include:

Dr. Emil D. W. Hauser, assistant professor of bone and joint surgery at Northwestern, Our Walk Through Life, August 1.

Dr. Leon Unger, assistant professor of medicine, Northwestern, Hay Fever and Prevention of Asthma, August 8.

Dr. Edward A. Piszczek, assistant professor of public health and preventive medicine, Loyola University School of Medicine, Infantile Paralysis, August 15.

Dr. H. William Elghammer, clinical professor of pediatrics at Loyola, Getting Along with Your Children, August 22.

Time Limit Extended for Hospital Trust.—The time in which the University of Chicago may build the projected Charles Gilman Smith Hospital for treatment of contagious diseases, without losing the income from a $500,000 trust fund left in 1907 by Mrs. Annie W. Durand for maintaining a wing of the institution, was extended July 10 for five years, or until June 28, 1950, by Judge Julius H. Miner in Circuit Court. According to the Chicago *Sun* the hospital, the construction of which was about to begin at the outbreak of the war, is to be built through the pooling of University of Chicago funds with funds from three estates: those of Mrs. Harriet G. Smith,

widow of Charles Gilman Smith; of Mrs. Durand, and of Robert McCormick, son of the late Harold F. McCormick and Edith Rockefeller McCormick. Mrs. Durand was the founder of the old Durand Hospital, at Flournoy and Wood streets, which was closed in 1933.

MARYLAND

Dr. Cameron Chosen Welfare Medical Care Officer.—Dr. William R. Cameron has been chosen assistant director of welfare for medical care, subject to approval by the city service commission, according to *Baltimore Health News*. Dr. Cameron, who has been serving with the U. S. Public Health Service as city health officer of Charlotte, N. C., formerly served as health officer for Hagerstown and Washington County. He was also director of the survey of medical care in the counties of Maryland. The welfare position is a newly created one.

MISSOURI

Representatives Pass Resolution for Physician.—The Missouri House of Representatives passed a resolution of respect on May 26 for Dr. George W. H. Presnell, mayor of Sikeston, who died May 26. The resolution eulogized Dr. Presnell for his service as alderman, mayor of Sikeston for three successive terms and his period of service as president of the Scott County Medical Society.

Appointments to State Board of Health.—Governor Phil M. Donnelly has made the following appointments to the state board of health for four year terms: Drs. George E. Knappenberger, Kansas City, to succeed Ira H. Lockwood, Kansas City; Frank H. Rose, Albany, to succeed John I. Byrne, St. Joseph, and Ralph A. Kinsella, St. Louis, to succeed Cleveland H. Shutt, St. Louis. Other members of the board include Drs. Robert M. James, Joplin, recently appointed state commissioner of health (THE JOURNAL, April 21, p. 1066); Charles H. Neilson, St. Louis; Howard B. Goodrich, Hannibal, and Hardin M. Henrickson, Poplar Bluff.

NEW YORK

Graduate Lectures.—Dr. Ellery G. Allen, Syracuse, will address a meeting of the staff of the Memorial Hospital of Greene County and the Greene County Medical Society in Catskill, September 27, on "Practical Considerations of Blood Dyscrasias." Dr. Ivan Hekimian, Buffalo, will address the two groups October 25 on "Practical Application of Hormonal Therapy." The meetings have been arranged by the council committee on public health and education of the state medical society.

New York City

Restrain Distribution of Spectrochrome.—The United States government was permitted on June 26 to restrain Dinshah P. Ghadiali, president of the Spectrochrome Institute of Malaga, N. J., from distributing his "all-curing machine" when an all woman jury returned a verdict in favor of the federal government in a civil action, according to the New York *Times*. Ghadiali was his own counsel and held that people can be healed by the spectrochrome machine through the use of colored lights. In summing up, assistant U. S. Attorney Morris K. Siegel said that Ghadiali "was a man preying upon the gullibility of people for his own personal profit. The federal government had taken action, he said, to stop gullible people from spending $90 for the purchase of the machine. The government has tried to show that this machine has no healing powers, but it was the imagination of many people that they were cured of their illnesses by submitting themselves to so-called treatment through this machine," Mr. Siegel stated.

Honor Memory of Lewis Stimson.—Dr. George J. Heuer, professor of surgery, Cornell University Medical College, has been appointed the first Lewis Atterbury Stimson professor of surgery, a position created under the will of Dr. Stimson's daughter, Miss Candace Stimson. The gift represents an endowment of more than $600,000 and will serve as a memorial to the first professor of surgery at Cornell, who held the position from 1898 to 1917, when he died. Coincidental with the announcement of the new professorship was one reporting the presentation of a portrait of Dr. Stimson to the college by Hon. Henry L. Stimson, Secretary of War, son of the late physician. Special ceremonies were held at the medical college to mark the presentation of the portrait and the endowment. Speakers included Dr. Lewis Atterbury Conner, a cousin of the late Dr. Stimson, Dr. Heuer and Dr. Philip M. Stimson. The late physician graduated at Bellevue Hospital Medical College in 1874. A personal friend of Pasteur, Dr. Stimson taught for many years as professor of physiology, anatomy and surgery at the University and Bellevue Hospital Medical College and in 1898 collaborated with the late Oliver H. Payne in founding the Cornell University Medical College.

Food Poisoning Traced to Cadmium Plated Pump.—The sudden illness of 5 persons after drinking strawberry soda at a soda fountain June 26 has been traced to the use of a cadmium plated syrup pump, according to the New York City Department of Health, July 12. All of the patients recovered. The New York City sanitary code forbids the use of cadmium on food utensils, refrigerator trays and similar items. Even a minute quantity of cadmium dissolved by the acid of fruit juice or syrup is capable of causing violent vomiting and severe distress. The investigation of the illness of the 5 persons, conducted by the health department, disclosed that all of the persons had become ill after drinking a strawberry soda made from syrup and carbonated water. No other foods had been eaten in common by any of the victims. The health department seized all pumps in the fountain for chemical examination, and it was found that the pump used for the strawberry syrup was cadmium plated. Syrup from the pump was also found to contain traces of the dangerous metal. Further investigation disclosed that the entire fountain unit containing the pump had not been used for eight years and had been placed in operation by the new owner of the fountain one week prior to the poisonings.

NORTH CAROLINA

G. M. Cooper Honored.—The woman's auxiliary to the Medical Society of the State of North Carolina recently named a bed at the Eastern North Carolina Sanatorium, Wilson, for Dr. George M. Cooper, Raleigh, assistant state health officer and director of the division of health education, state board of health.

Personal.—Dr. James A. Whitaker has resigned as health officer of Rocky Mount to join the staff of the Columbia Presbyterian Hospital, New York.——Dr. Louis G. Beall was recently named acting superintendent of the State Hospital at Morganton, succeeding Dr. John R. Saunders, resigned (THE JOURNAL, April 28, p. 1140).

OHIO

Personal.—Col. Harold Wellington Jones, M. C., librarian of the Army Medical Library, Washington, D. C., received the honorary degree of doctor of laws during the commencement of Western Reserve University, Cleveland, June 13.

New Departments Created at Western Reserve.—Through the division of the department of hygiene and bacteriology at Western Reserve University School of Medicine, Cleveland, two new departments have been created, the department of preventive medicine and public health and the department of bacteriology. Dr. James A. Doull, as head of the new department of preventive medicine and public health, will fill the newly created Elizabeth Severance Prentiss chair in preventive medicine. The department will be financed by an annual income from the Elizabeth Severance Prentiss Fund. An announcement from Western Reserve University states that the details of the organization of the department of bacteriology and the appointment of a director will be announced later. The department of hygiene and bacteriology at Western Reserve was established in 1910 as an offshoot of the department of pathology.

SOUTH CAROLINA

Personal.—Dr. Joseph I. Waring, Charleston, has been appointed by Governor Ransome J. Williams as a member of the state board of health to succeed Dr. Kenneth M. Lynch, Charleston, it is reported.

Dr. Rhame Resigns as Professor of Surgery.—Dr. Joseph Sumter Rhame has resigned as clinical professor of surgery at the Medical College of the State of South Carolina, Charleston. Dr. Rhame has been associated with the school since 1910.

License Revoked.—The South Carolina State Board of Medical Examiners reported on May 21 that the license to practice medicine or Dr. Perry M. Workman, Lyman, was revoked as of April 17 for violation of his probation on a narcotic charge.

Health Department Celebrates Twenty-Fifth Anniversary.—The Charleston County Health Department observed its twenty-fifth anniversary recently. Dr. Leon Banov, health officer, has held the position since the department was organ-

ized In 1926 the county and city health departments were merged and ten years later the city department was abolished, giving the county group charge of health for both the city and the county of Charleston

Society Incorporates—Creates New Foundation.—The Greenville County Medical Society at its meeting in June voted to incorporate The society also authorized the establishment of a trust fund to be known as the Medical Foundation Proceeds from the fund will be used for "scientific, educational and charitable purposes, including the promotion of the science of medicine, assisting medical students, the establishment of a medical library and the construction of a building for such purpose or purposes"

WASHINGTON

Emil Palmquist Named Health Commissioner of Seattle.—Dr Emil E Palmquist, health officer of King County, was on July 1 appointed commissioner of health for the city of Seattle Dr Ragnar T Westman has been acting city health commissioner on leave from the U S Public Health Service

Physicians Denied Injunction in Medical Society Suit.—On June 15 a temporary injunction by which they sought authority to practice in the Renton Hospital until trial of their court action was denied Drs John M Howell and Roy H Blender, Renton Superior Judge Robert M Jones refused to grant the temporary restraining order to prevent the physicians from being barred from practice in the hospital, and their attorney, Gerald De Garmo, is reported to have said that the judge's denial will be used as the basis for a motion for an advanced setting of the case on the superior court calendar, according to the Seattle *Times* The case was reported in THE JOURNAL, July 7, page 743, and involves a suit against the King County Medical Society and the King County Medical Service Corporation, both of which have been accused by the physicians of conspiring to acquire a "monopoly" for members of the society in practicing medicine in the county and to "eliminate competition" in furnishing medical and hospital services to the public on the prepayment or monthly payment plan

WEST VIRGINIA

Library of Public Health Education.—For the first time in the history of the West Virginia State Health Department a reference and lending library has been established in the bureau of public health education in line with similar action taken by the health departments of many other states For the present the library will be maintained for the use of the personnel of the state health department, but eventually it is planned to make the facilities available to the physicians in West Virginia

Changes in Division Heads of Health Department.—Dr Glenn A Carmichael, Butte, Mont, has been appointed director of the division of maternal and child hygiene of the West Virginia State Department of Health, succeeding Dr Lenore V L Patrick-Chipman, who resigned some months ago to engage in private practice at Williamstown, Ky (THE JOURNAL, June 24, 1944, p 589) Dr Norman G Angstadt, director of county health work, has been acting director of the division (THE JOURNAL, Oct 7, 1944, p 378) since Dr Chipman resigned —— Dr Robert L Smith, U S Public Health Service, has been appointed acting director of the bureau of tuberculosis to succeed Dr James T Duncan, resigned Dr Smith, who has been assistant director of the bureau since April, was connected with the division of tuberculosis control of the United States Public Health Service, Bethesda, Md, for two years before coming to West Virginia He recently completed a course in the school of public health at the University of Michigan Several divisions and bureaus of the state health department have moved to downtown Charleston to provide space for expanding agencies left at the capitol Twelve rooms have been rented in the Virginia Land Bank Building at the corner of Capitol and the Boulevard to house the bureau of venereal diseases, division of communicable diseases bureau of industrial hygiene, division of maternal and child hygiene, the nutrition consultant and the midwife consultant The division of industrial hygiene remains at 1584 East Washington Street while the bureau of tuberculosis has been moved to 1719 Washington Street The division of public health education is now located at 300½ Duffy Street having been moved from the capitol to provide more room for the division of vital statistics, the bureau of county health work and the division of finance

GENERAL

Leslie Dana Gold Medal Goes to William Zentmayer.—The Leslie Dana Gold Medal will be presented this year to Dr William Zentmayer, professor emeritus of diseases of the eye, University of Pennsylvania Graduate School of Medicine, Philadelphia The medal is awarded on the recommendation of the Association for Research in Ophthalmology and given to the recipient by the St Louis Society for the Blind Dr Zentmayer has, among other positions, served as president of the American Ophthalmological Society and chairman of the Section on Ophthalmology of the American Medical Association Conditions of the gold medal award set forth that it is to be made for "long meritorious service in the conservation of vision, in the prevention and cure of diseases dangerous to eyesight, research and instruction in ophthalmology and allied subjects, social service for the control of eye diseases, and special discoveries in the domain of general science or medicine of exceptional importance in conservation of vision"

Red Cross Chapters to Recruit Blood Donors for Civilians.—American Red Cross chapters throughout the nation will be permitted to recruit blood donors for civilians under a program announced by Mr Basil O'Connor, chairman of the American Red Cross Under this project any Red Cross chapter may take part in the operation of a donor center for civilians sponsored by a recognized medical or health agency The blood collected and the blood derivatives produced will be made available without cost to physicians, hospitals, clinics and patients This civilian program is entirely separate from the Blood Donor Service operated by the American Red Cross for the armed forces, it was stated, and chapters in the eleven metropolitan centers where the Red Cross is now recruiting donors for the Army and Navy will not participate in it These are Los Angeles, San Francisco, Oakland, Portland, Ore, San Diego, Chicago, New York, Brooklyn, Boston, Philadelphia and Washington Assistance in establishing standards and conducting a civilian program will be made available to chapters through the five Red Cross area offices The new project will be supervised by an advisory committee of specialists to be appointed

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended July 14 have been received from the division of public health methods, U S Public Health service, as follows

Maine	1	South Carolina	11
New Hampshire		Georgia	8
Vermont	1	Florida	1
Massachusetts	2	Kentucky	
Rhode Island		Tennessee	27
Connecticut	4	Alabama	6
New York	29	Mississippi	2
New Jersey	23	Arkansas	3
Pennsylvania	4	Louisiana	1
Ohio	10	Oklahoma	7
Indiana	1	Texas	45
Illinois	4	Montana	
Michigan	1	Idaho	1
Wisconsin	1	Wyoming	1
Minnesota		Colorado	1
Iowa	1	New Mexico	
Missouri	1	Arizona	
North Dakota		Utah	
South Dakota		Nevada	0
Nebraska		Washington	5
Kansas	5	Oregon	2
Delaware	1	California	22
Maryland	3		253
District of Columbia	6	Total	462
Virginia	7	1944	1 677
West Virginia	3	Total to date	1 752
North Carolina	2	Same period 1944	

Italian Medical Nutrition Mission—Dr James E Perkins, director of the division of communicable diseases, New York State Department of Health, Albany, began a leave of absence June 15 to go to Italy to serve on the Italian Medical Nutrition Mission, which is studying health problems that have developed in the country following the war and is aiding in the establishment of a program for their control Dr Perkins has been commissioned as a reserve officer for the purpose by the U S Public Health Service and assigned to the United Nations Relief and Rehabilitation Administration, under which the mission is operating Dr Perkins plans to be in Italy for three months as co-epidemiologist of the mission to continue activities which have been conducted over a similar period by Dr Ernest L Stebbins, health commissioner of New York City, who accompanied the first contingent which left in April and should be back in July The co directors of the mission are Drs Elmer L Severinghaus Madison, Wis and Maurice B Visscher, Minneapolis *Health News* of the New York State Department of Health reports that the work of the mission is being financed in part by two church organizations,

the Unitarian Service Committee and the Congregational Christian Service Committee. These agencies are furnishing much of the equipment and supplies and paying the salaries of many members of the mission.

Availability of Film.—The American College of Radiology announces that the production schedules in film allotments for the third quarter of the present year indicate that quotas for civilian physicians and hospitals have been appreciably increased. WPB allotments for civilian consumption of medical radiographic film during the last quarter of 1944 amounted to 9.2 million square feet. Owing to the fact that manufacturers were unable to meet these schedules, only 9 million square feet was actually shipped. In the first quarter of 1945, 9.7 million square feet was allotted for civilian consumption. Total shipments were 9.2 million square feet. Shipments for the second quarter of 1945 are not yet known, but it is undoubtedly somewhat less than the 9.4 million square feet allotted. For the third quarter of 1945, 10.6 million square feet has been allotted for civilian health services. If manufacturers are able to meet these schedules, radiologists should be able to obtain almost all the film they require, assuming that they effect all possible economies. The college estimates that 11 million square feet per quarter would meet minimum requirements of civilian physicians and hospitals. The allotment for the Army and Navy for the third quarter is not definitely known. For the army industrial program, 5 million square feet has been allotted for ordnance inspection. UNRRA will receive 500,000 square feet. The quota for FEA and Lend-Lease has been sharply reduced. It is estimated that about 24 million square feet of medical radiographic film will be produced during the third quarter. Radiologists who are unable to obtain sufficient film to maintain their services should continue to report their cases to the headquarters office of the college, 20 North Wacker Drive, Chicago 6. All such cases will be referred to the proper officials of the WPB.

Sugar Research Foundation Allots Grants.—More than $50,000 will be available for seven universities and laboratories by the Sugar Research Foundation, New York, according to an announcement July 16. The studies to be pursued under the new grants will seek new industrial uses of sugar and further explore the nutritional values of sugar. Eight of the projects call for allotments totaling $41,500. Specific use of the grants includes:

Dr. Hans Selye, associate professor of histology, McGill University Faculty of Medicine, Montreal, $10,000 for a three year study of the effects of diets in protecting animals from the effects of overactivity of the endocrine glands.

Dr. Israel M. Rabinowitch, associate professor of medicine at McGill, $10,000 for investigation of the use of sugars in human nutrition in health and in disease.

Gebhard Stegeman, Ph.D., professor of physical chemistry at the University of Pittsburgh, $7,000 to collate all existing data and carry out new measurements of the physical properties of sugar and sugar solutions for use by industrial chemists.

Frederick W. Zerban, Ph.D., and Louis Sattler, Ph.D., New York Sugar Trade Laboratory, New York, $4,000 for further investigation of the unfermentable constituents of molasses.

George R. Cowgill, Ph.D., professor of nutrition, Yale University School of Medicine, New Haven, $3,600 to survey the vitamin content of various products of the sugar industry at the point where they reach the market.

Leo T. Samuels, Ph.D., head of the biochemistry department at the University of Utah, Salt Lake City, $3,500 to study the capacity of animals to adjust themselves physiologically to various types of diets.

Heinz M. Wuest, Ph.D., Brooklyn Polytechnic Institute, $1,900 to study preparation of several compounds closely related to vitamin B_1 and study their effects on assay methods.

Walter D. Bonner, Ph.D., and Ralph F. Phillips, Ph.D., of the chemistry department at the University of Utah, $1,500 to study production of certain glucose derivatives directly from sugar and molasses.

Dr. Luther Emmett Holt Jr., New York, an additional $5,000 to continue his work on the synthesis of vitamins in the intestinal tract under the influence of various diets.

James M. Neill, Ph.D., professor of bacteriology and immunology, Cornell University Medical School, New York, renewal of a $4,500 grant.

LATIN AMERICA

Health Activities in Latin America.—*Maternal and Child Health Services in Rural Districts.*—The first of a proposed series of maternal and child health stations in the rural districts of Peru recently began to function in the town of Tingo Maria. The staff of the station consists of a graduate child health worker, a midwife and two assistants. Their work is chiefly educational, and most of it is done through visits to the homes of the rural workers. The child health worker and the midwife instruct the women in antepartum and infant care, in general hygiene and in ways of improving their families' living conditions.

Course on Phthisiology.—The first Argentine Congress on Phthisiology will be held in Buenos Aires in November, the exact dates to be determined later. The congress is to be sponsored by the Sociedad Argentina de Tisiologia with the cooperation of the National Department of Public Health against tuberculosis and of the societies against tuberculosis in the various provinces and hospitals of Argentina. Headquarters of the congress are located at Avenida Velez Sarsfield 405, Buenos Aires.

Health Center Named for General Dunham.—On April 6 the Health Center General Dunham was dedicated, according to the *Newsletter* of the Health and Sanitation Division of the Institute of Inter-American Affairs. The center was constructed by the Servicio Cooperativo Inter-Americano de Salud Publica in Asuncion, Paraguay, and named in honor of Gen. George C. Dunham, M. C., president of the Institute of Inter-American Affairs. General Dunham spoke at the dedication ceremonies.

School of Hygiene Dedicated.—The School of Hygiene, Santiago, Chile, organized in 1944 through the cooperative efforts of the University of Chile, the Rockefeller Foundation, the Bacteriological Institute and the U. S. Public Health Service, was opened May 11, according to the *Newsletter* of the Health and Sanitation Division of the Institute of Inter-American Affairs. The school was equipped and constructed by the Departamento Cooperativo Interamericano de Obras de Salubridad at a cost of $85,000. It will offer undergraduate and postgraduate courses leading to a degree of master of public health. Speakers at the opening included Dr. Theodore I. Gandy, chief of field party in Chile and head of the Departamento Cooperativo Interamericano de Obras de Salubridad; Nacianceno Romero, director of health; Eugenio Suarez, director of the Bacteriological Institute; Lewis W. Hackett, director of the Rockefeller Foundation for Rio de la Plata and the Andean region; Armando Larraguibel, dean of the school of medicine, University of Chile, and Hernan Romero, director of the school of hygiene.

Meeting of Academy of Surgery.—Three American physicians were among the eight new members accepted into the Mexican Academy of Surgery at a ceremony held on June 12 in the auditorium of the National University Faculty of Medicine, *Mexico City, in celebration of the twentieth anniversary of the* founding of the society. The Americans, who were titled as foreign correspondents of the academy, are Drs. Julius L. Spivack, Chicago, Chevalier L. Jackson, Philadelphia, and Paul H. Holinger, Chicago. The new Mexican members are Drs. Fernando Valdes Villareal, Donato Ramirez, Ignacio Cadena, Manuel Medina Gutierrez and Inocencio de Lara. Dr. Jose Torres Torija, permanent secretary of the organization, delivered the speech of welcome to the initiates.

Penicillin Distribution Changed.—Mexican patients are now able to obtain penicillin at any drugstore on their physician's prescription under a decision of the Mexican government to free the drug from all bureaucratic control. Up to now the supply has been controlled by the federal ministry of public health and public welfare and a committee of three physicians who were entrusted with its distribution to the profession. Since the quantity on hand is believed to be more than enough to satisfy the country's demand, the government has ordered it made available to the general public under medical supervision. A top retail price has also been fixed at 11.50 pesos (approximately $2.30) per hundred thousand units. Private practitioners are given a special price of 5 pesos per hundred thousand units of penicillin for office use, effective on July 1.

Health Films for Institute of Inter-American Affairs.—A series of ten animated health films entitled "Salud para las Americas" (Health for the Americas) has been produced by the Walt Disney Studios for the Institute of Inter-American Affairs. The first eight of these films were released during May and June and the last two will be released during September. The titles are "The Human Body," "What is Disease," "Tuberculosis," "Infant Care," "How Disease Travels," "Cleanliness Brings Health," "Hookworm," "Insects as Carriers of Disease," "Environmental Sanitation" and "Nutrition." Although contributions from many sources have gone into the final production, these ten animated films are primarily the work of Capt. Ryland R. Madison, S. C., and Dr. Janet W. Mackie of the institute and Mr. Ben Sharpsteen of Walt Disney Productions.

CORRECTION

Military Rank Omitted.—The military rank of Dr. Ronald L. Denton should have been included at the end of the communication to the editor on "Treatment of Erythroblastosis Fetalis" in THE JOURNAL, June 30, page 686, as follows: Surgeon Lieutenant Commander Ronald L. Denton, R. C. N. V. R.

The Future of Psychiatry

The Royal College of Physicians, the British Medical Association and the Royal Medico-Psychological Association during the past year have been formulating their views on the future of psychiatry. As these views are so similar, it was decided to publish them in a joint memorandum. This points out that in recent years psychiatry has been brought into increasingly close relation with general medicine. Historically psychiatry developed as the method of treatment of those whose mental illness necessitated segregation. It is now recognized that this distinction, however important socially, is medically irrelevant, for there is only a difference of degree between the majority of the patients in a mental hospital and the far more numerous sufferers from less severe mental disorders outside. The proportion of the general population requiring treatment in mental hospitals is 3.9 per thousand. But much more psychiatry needs to be done outside than inside these hospitals. At the same time psychiatry has shown that it has much to contribute to research into the causes and treatment of many forms of illness formerly regarded exclusively from the medical or surgical point of view.

The following recommendations are made: 1. Psychiatry is not a limited specialty. It permeates and influences general medicine, surgery, obstetrics and gynecology. Psychiatrists should be appointed to the staffs of general hospitals with status equal to that of other physicians and surgeons. 2. The mental health department of the health service of the future should be responsible for the organization of all medical work which is essentially psychiatric. 3. The psychiatrist is not concerned merely with fully developed mental disorders. The mental health service should include provision for prophylaxis of mental disorders over the widest field. 4. In the educational sphere psychiatric advice is essential for children showing neurosis, behavior disorder or mental defect. 5. In industry a full and efficient consultative psychiatric service should be available, which should work in close cooperation with the patient's doctor and the industrial medical officer. Psychiatrists should cooperate with industrial psychologists in the investigation of industrial fatigue and ill health, working hours and conditions, incentives, personnel management and the like. 6. Psychiatrists should cooperate in the work of vocational guidance and selection, an essential part of which is the assessment of personality and temperament. 7. Psychiatrists should take part in the rehabilitation of patients after accident or illness. This work should be carried out in close liaison with employers, workers' representatives and patients' doctors.

The Control of Science in Germany

In the House of Lords during a discussion on the prevention of scientific developments in Germany for the purpose of war Lord Vansittart said that unless this was done even more potent secret weapons would be produced. Provision should therefore be made to guard against granting permission to develop devices potentially dangerous. He advocated control of all German laboratories, university and industrial, through an intelligence service of the united nations. Lord Brabazon was more specific and discussed particularly the "directed missile" in the form of the flying and rocket bomb. He therefore suggested, as part of the peace organization, an international inspectorate with power to enter works anywhere in the world.

Lord Cherwell replied for the government. He said that a scientific committee had been appointed a year ago to consider the whole question of scientific research in Germany, and a preliminary report would soon be ready. Any proposals must be discussed with our allies. A scientific and technical staff had been attached to the headquarters of the Allied Expeditionary Forces to examine and control German activity in these fields.

The Increased Birth Rate

In surveying retrospectively the national health during five and a half years of war, Minister of Health Willink reported in the House of Commons that the birth rate had been rising since 1941 and last year was the highest since 1925 and within 1 per cent of full replacement. Not only had more babies been born but fewer had died. The chance of a baby being born dead was only three fourths of what it was six years ago, he said. Also fewer mothers were being lost in childbirth. All the vital statistics for mothers and children were the best this country had ever known.

THE NETHERLANDS

(From Our Regular Correspondent)

May 10, 1945.

Five Years of Enemy Occupation

Five years have passed since the invasion. Before the war the physicians were organized in the Maatschappy tot Bevordering der Geneeskunst (Society for the Advancement of Medicine). Very gradually the Germans tried to nazify the organization, with the result that 95 per cent of all the physicians joined the secret organization known as M. C. (Medical Contact). The central committee of this underground organization gave its directives in the closest contact with other underground organizations, the churches and so on, and in this way it became possible that, for instance, at the same hour in the whole country all the physicians removed the signs at their doorsteps in protest to the German attempt to incorporate them in the nazi "artsenkamer." The result was that the Germans failed completely in their attempts in all respects. The membership of M. C. and the other underground activities caused a great many deaths among us. Many had to "dive," as we called it, and this, combined with the closing of the universities since 1942, caused a considerable decrease in the number of physicians.

A great handicap was the loss of contact with the outside world. Only German medical literature was available, and so it happened that for many of us the first report of the existence of penicillin arrived by means of the British Broadcasting Company and pamphlets dropped by the Royal Air Force. The future, however, will give proof of the scientific activities of our medical community. In the field of intravenous therapy, in the treatment of fractures, in chest surgery, in the treatment of uremia, an x-ray device for a very exact localization of metal foreign bodies was either developed or adopted.

No official records are yet known as to the state of health of the population. Many data about deaths, births and domiciles were often deliberately falsified or destroyed. Public administration became chaotic, and it therefore becomes clear that, e. g. in the Hague, the number of fatal bombardment casualties is still a guess. It will take quite a long time before we can get at the exact data about the medical situation. Generally speaking there was an increase in tuberculosis and infectious diseases (especially diphtheria and scarlet fever). The increase in venereal diseases was evident despite the fact that only a limited number of women was involved. A strict control by the state hygienic authorities isolated a few cases of typhus and typhoid and protected the population effectively. Allied and enemy air action caused a great many casualties. The death rate of the newborn and young children increased also.

Our hospitals and sanatoriums did what they could, but they were greatly handicapped by the lack of personnel, equipment,

drugs, dressing material and instruments. At the outbreak of war we had a large store of food, drugs—for instance, insulin—but they were used for the Germans. Only the urgent cases could get hospital treatment. Temporary hospitals were erected for chronic patients. During 1944 and 1945 the food supply decreased sharply, with the result that especially in the large cities like Amsterdam, Rotterdam and the Hague the population starved. In the city of Amsterdam (750,000 inhabitants) a conservative estimate gives a mortality to the present of 10,000.

BOLIVIA

(From Our Regular Correspondent)

LA PAZ, July 6, 1945.

Hospital Facilities in Bolivia

Figures regarding hospital facilities in Bolivia recently were made available, the first since 1942. The present figures are based on those collected by the Vital Statistics Department of the Bolivian Health Ministry under the direction of Mr. Hubert E. Navarro, to be presented to this year's congress.

Under government control there are now operating thirty-six hospitals with a combined bed capacity of 3,347, against thirty-five such hospitals with a capacity of 3,236 beds in 1942. This means there are at present 1.12 beds available for every thousand inhabitants. The individual capacity of these hospitals varies between 550 beds, as in the La Paz General Hospital, and 5 beds. There are thirty-one general hospitals with a combined capacity of 2,779 beds, one hospital for the treatment of mentally ill with 236 beds, one children's hospital with 80 beds, two hospitals for cases of tuberculosis with a total of 210 beds, and an eye hospital with 33 beds.

There is a total of twenty privately owned hospitals with a combined capacity of 601 beds, representing 15.2 per cent of the total beds available. Of this number nine clinics are operated on a proprietary basis; one, caring especially for poor children and operating a free delivery service, is operated by a nonprofit organization.

No figures on admission rate, length of stay or similar statistics are available, or on the number of registered nurses, orderlies, laboratory technicians and other hospital personnel. The occupancy rate is probably rather high because of the relatively few hospital facilities, the public hospitals being therefore constantly fully occupied.

There are three schools for nursing education, two of them operating attached to public hospitals and one in connection with a private clinic, with a combined student enrolment of about 120 girls.

The general director of health, Dr. Debbe, is developing a program of new hospital facilities, including a leprosarium and expanding existing services. Some of these projects are helped through the coordinator's health program. There is a special project for starting free delivery stations all over the country.

Number of Physicians and Other Health Officers in Bolivia

Published by the Bolivian Health Ministry were figures concerning physicians, pharmacists and other health officers at work during the month of October 1944. An average of 1.48 physicians is available to take care of 10,000 inhabitants, an average of 6,810 inhabitants being attended by every registered doctor. There are large parts of the population distributed in such a manner over wide parts of the national territory that it would be difficult if not impossible to offer them any medical attention at all; this is especially true regarding the tropical regions of Beni and Pando, situated on the Brazilian border and covered mostly by bush, where the density of population is less than 1 per square kilometer, and the only ways of communication are the rivers and the airlines.

The total number of physicians and other registered health officers has greatly improved since 1942, when a similar survey was made. The number of physicians has increased from 471 in 1942 to 528 in 1944. Not included are the physicians, enrolled with the Bolivian armed forces, who attend civilians in places where no other physician is yet established. The health authorities also allowed some refugee physicians to work in places where no other licensed physician is available, locating them mostly in the tropical regions. Some help in public health work is also offered by institutions such as the Coordinator's Health Division, which is at present employing 2 to 3 doctors and some nurses right in the bush regions, as well as the Rockefeller Foundation, which for years, under the direction of Dr. Henry P. Carr has performed a most important sanitation work through its yellow fever, malaria and uncinariasis services.

Visitors to the United States

Dr. Guillermo Debbe, Bolivian surgeon and general director of health of the country, is going to visit the United States soon, following an invitation made by the coordinator's office. On his trip, planned also by the coordinator, Dr. Debbe will see especially establishments concerning preventive medicine, and he will be most interested in studying the details of organizing public health institutions and health authorities. He has been organizing in this country the existing public emergency service and the health department. On his way back he will also visit Mexico, Cuba, Venezuela and Peru.

Dr. Carlos Ferrufino, who has been general inspector of health in Bolivia, is to join the UNRRA displaced persons program. Dr. Ferrufino only recently returned from the United States, where he finished postgraduate studies on a scholarship at Harvard. He will leave soon for Washington, D. C., on his way to Europe.

Marriages

WILLIAM MERRILL CORRY WILHOIT, Quincy, Fla., to Miss Martha Elizabeth Watkins of Valdese, N. C., in Durham, N. C., June 23.

PHILIP VINCENT DAUGHERTY, Nashville, Tenn., to Miss Rosemary Rita Levitt of Villa Ridge, Ill., in St. Louis, June 4.

HIRAM BARRINGER VAN DEUSEN, Canandaigua, N. Y., to Miss Muriel Ehrich of Newark, N. J., recently.

RAMSAY GARRISON LATIMER, West Columbia, S. C., to Miss Jean Neuman Mehrtens of Charleston, June 16.

WELLINGTON B. STEWART, Evanston, Ill., to Miss Helen M. Zimmerman of Spencerport, N. Y., June 16.

JULIAN MULDROW DURANT, Alcolu, S. C., to Miss Marie Elizabeth Beckett of Beaufort, June 19.

LEEWAN ROBERT KELLAM, Culver, Ind., to Miss Emily Taylor Richardson of Raleigh, N. C., June 16.

BEVERLY C. CHATHAM, Greenville, Ky., to Miss Janet Johnson of Nashville, Tenn., June 20.

LEWIS GEORGE RICHARDS JR., Roanoke, Va., to Miss Dorothy Nelle Quinn of Lynchburg, June 23.

CHARLES A. DWYER JR., Houston, Texas, to Miss Virginia Dean of Hollywood, Calif., April 21.

THOMAS E. WYATT JR., Marshfield, Wis., to Miss Pauline M. Ciola in Fort Pierce, Fla., June 18.

HARVEY RAY ST. CLAIR to Miss Pauline Carroll Keller, both of Staunton, Va., June 23.

WILLIAM L. CHEEZEM JR., Andrews, S. C., to Miss Louise McBrayer of Columbia, June 9.

ROBERT LESLIE CRAIG, Honolulu, Hawaii, to Miss Rita Beryl Knight in Akron, Ohio, June 16.

PALUEL J. FLAGG, Yonkers, N. Y., to Miss Marcella V. Devlin in Harrison, June 27.

ALBERT STEPHAN TERZIAN to Miss Ellen Ruth Skilton, both of Philadelphia, June 15.

JACK DENIS FLYNN to Miss Stella Rosalie Valenti, both of Tampa, Fla., June 20.

Deaths

Alexander H. Beam, Cincinnati; Medical College of Ohio, Cincinnati, 1890; for many years associated with the Warren E. Richards Company, realtors, as sales manager and director; died May 7, aged 83, of carcinoma of the sigmoid and the descending colon.

Seth Douglas Beavers ⊕ Decatur, Ind.; Rush Medical College, Chicago, 1886; honorary member of the Indiana State Medical Association; died May 12, aged 84, of congestive heart disease and chronic myocarditis.

Julian Lee Birdsong, Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1909; died in the Veterans Home, Rocky Hill, May 17, aged 69, of coronary occlusion.

Vernon Blythe, Paducah, Ky.; University and Bellevue Hospital Medical College, New York, 1900; member of the American Medical Association; served as a member of the state board of health; past president of the Southwestern Kentucky Medical Association; at one time secretary of the McCracken County Medical Society; served during World War I; formerly chairman of the municipal housing commission and past president of the board of education; died in the Illinois Central Hospital May 3, aged 68, of lobar pneumonia.

Nathan Leander Bourne ⊕ Decatur, Ill.; Barnes Medical College, St. Louis, 1903; served on the staffs of the Decatur and Macon County Hospital and St. Mary's Hospital; died May 17, aged 71, of circulatory failure.

Lemuel Brehaut, White Plains, N. Y.; University of the City of New York Medical Department, New York, 1887; died June 13, aged 83, of generalized arteriosclerosis.

Cecil Else Brous ⊕ Portland, Ore.; University of Oregon Medical School, Portland, 1913; died June 3, aged 55, of nephritis.

Charles Roscoe Buren, Princeton, Mo.; St. Louis College of Physicians and Surgeons, 1896; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; at one time associated with the Indian Service; died in Atlanta, Ga., June 8, aged 71, of coronary occlusion.

Roscoe Patrick Carney, Davenport, Iowa; St. Louis College of Physicians and Surgeons, 1911; served as president and secretary of the Scott County Medical Society; member of the American Medical Association, Iowa Sanatorium Association, American College of Chest Physicians and the American Trudeau Society; served as president of the alumni association of St. Ambrose College; for many years medical director of the Pine Knoll Sanatorium; on the staffs of the Mercy and St. Luke's hospitals; died in Firman Desloge Hospital, St. Louis, June 12, aged 60, of progressive pulmonary fibrosis, heart disease and terminal pneumonia.

Walter Scott Conn, Los Angeles; Chicago College of Medicine and Surgery, 1914; served during World War I; formerly associated with the U. S. Public Health Service Reserve; died May 10, aged 78, of heart disease.

George D. Counts ⊕ Wesley, Ark.; Marion-Sims College of Medicine, St. Louis, 1897; secretary of the Madison County Medical Society; on the staff of the Fayetteville City Hospital, Fayetteville; died April 18, aged 73, of carcinoma.

George L. G. Cramer, Owosso, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; member of the American Medical Association; for many years county coroner; past president of the Shiawassee County Medical Society; past president of the Shiawassee County Conservation Association; instrumental in the founding and for many years active on the staff of the Memorial Hospital, serving for two years as chief of the staff; died April 3, aged 80.

Ernest Charles Dalton, St. Helens, Ore.; Willamette University Medical Department, Salem, 1905; formerly a contract surgeon in the U. S. Army; served on the Mexican border in 1916 and during World War I; died in St. Helens General Hospital May 16, aged 72, of cardiovascular disease.

John L. Daniels, Jefferson, Wis.; Milwaukee Medical College, 1905; for many years city physician; died May 16, aged 64, of arteriosclerosis and diabetes mellitus.

Willis Irving Dillingham, West New York, N. J.; Dearborn Medical College, Chicago, 1906; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; local school physician; died in Secaucus May 21, aged 76, of nephritis and arteriosclerosis.

George H. Ellis, Oilton, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; served a term as mayor of Oilton; died in Stillwater, March 31, aged 73, of cardiac failure and carcinoma of the leg.

Alfred Eugene Ewing, McDonald, Ohio; Cleveland Medical College, 1896; member of the American Medical Association; surgeon for Carnegie-Illinois Steel Corporation; past president of the local school board; served as director of the Federal Bank and First National Bank in Girard; died May 23, aged 75, of coronary disease.

John Bartow Fattic, Anderson, Ind.; Medical College of Ohio, Cincinnati, 1884; member of the American Medical Association; directed the organization of a hospital unit during World War I, serving overseas as a major; later promoted to lieutenant colonel; for many years chief surgeon for the Indiana Union Traction Company, examiner for many insurance companies and member of the staff of St. John's Hospital, where he died May 10, aged 82, of cerebral hemorrhage.

John Vernon Ferrell, Eldorado, Ill.; Chicago College of Medicine and Surgery, 1917; member of the American Medical Association; served as president of the Saline County Medical Society; member and past president of the Eldorado Rotary Club; medical director and part owner of the Eldorado Hospital; died May 8, aged 55, of carcinoma of the liver.

Maynard A. Finley ⊕ Emporia, Kan.; St. Louis College of Physicians and Surgeons, 1897; died April 26, aged 75, of chronic nephritis.

Harvey John Flowers ⊕ Kilmichael, Miss.; Memphis (Tenn.) Hospital Medical College, 1897; died in West Point March 25, aged 73.

Ellen Bellows Foot, New Rochelle, N. Y.; Cornell University Medical College, New York, 1938; member of the American Medical Association; diplomate of the National Board of Medical Examiners; assistant professor of surgery (anesthesia) at her alma mater; served a residency at the Massachusetts General Hospital in Boston and the Presbyterian Hospital in New York; interned at the New York Hospital, New York, where she served as anesthetist in chief and where she died May 11, aged 32, of primary carcinoma of the liver.

Rodolphus Wickham Fuller ⊕ Grand Rapids, Mich.; Detroit College of Medicine, 1909; served as head physician at the Indiana State Reformatory Hospital, Pendleton, and on the staff at St. John's Hospital in Anderson; on the staffs of Blodgett Memorial and St. Mary's hospitals; died in the Butterworth Hospital April 29, aged 58, of coronary occlusion.

Adolph Otto Goldstein ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1906; associate in laryngology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; on the staffs of the Northern Liberties and St. Luke's hospitals; died in the Doctors Hospital May 19, aged 63, of coronary thrombosis.

Thurman Bishop Haas, McArthur, Ohio; Jefferson Medical College of Philadelphia, 1913; served overseas as a major in the medical corps of the U. S. Army during World War I; died March 15, aged 58.

Edward Eli Heiple, St. Louis; St. Louis University School of Medicine, 1914; member of the American Medical Association; on the staffs of the Alexian Brothers' and St. Anthony's hospitals; died in Jefferson Barracks, Mo., May 4, aged 56, of hypertensive and arteriosclerotic heart disease.

Beverly A. Henry, Anderson, S. C.; Atlanta (Ga.) Medical College, 1886; honorary member of the South Carolina Medical Association; member of the American Medical Association; served as president of the city chamber of commerce; died in the Anderson County Hospital April 4, aged 82, of coronary thrombosis.

Samuel Beck Herdman, Taylorville, Ill.; Rush Medical College, Chicago, 1909; served during World War I; fellow of the American College of Surgeons; chief surgeon for the Peabody Coal Company; past president of the Christian County Medical Society; on the staff of St. Vincent's Hospital; died May 18, aged 63, of cerebral hemorrhage.

Henry Leon Hirsch ⊕ Springfield, Mass.; Jefferson Medical College of Philadelphia, 1906; at one time member of the city school committee; served during World War I; died May 8, aged 60, of coronary thrombosis.

George Llewellyn Hoffman Sr., ⊕ Norristown, Pa.; Jefferson Medical College of Philadelphia, 1904; past president of the Montgomery County Medical Society; on the staffs of the Montgomery and Sacred Heart hospitals; formerly on the staff of the Graduate Hospital of the University of Pennsylvania, Philadelphia; veteran of the Spanish-American War; died May 17, aged 77, of coronary thrombosis.

Arcturus Lee Howard, Chevy Chase, Md.; Georgetown University School of Medicine, Washington, D. C., 1893; retired in 1940 as head of the business practice department of the District of Columbia high schools; served on the staff of the Emergency Hospital and Central Dispensary in Washington, D. C.; died May 31, aged 75, of uremia, cerebral hemorrhage and cardiovascular-renal disease.

Boyd Merrill Krout, Stockton, Calif.; Harvard Medical School, Boston, 1913; member of the American Medical Association; served overseas during World War I; formerly on the staff of the San Joaquin General Hospital in French Camp; assistant health officer of the San Joaquin health district, with which he had been connected since 1927; died May 4, aged 60.

Oscar Adair Lashley, Steubenville, Ohio; Ohio State University College of Medicine, Columbus, 1924; member of the Student Army Training Corps during World War I; secretary of the Jefferson County Medical Society, 1927-1928, and president in 1929; died March 20, aged 46.

George Emerson Learn, Hamburg, N. Y.; University of Buffalo School of Medicine, 1904; member of the American Medical Association; retired member of the Medical Society of the State of New York; at one time served as principal of Stevensville, Ont., schools; formerly health officer of Hamburg; died in Our Lady of Victory Hospital, Lackawanna, May 27, aged 73, of heart disease.

Ada Belle Blair Mackey, Altoona, Pa.; University of Pittsburgh School of Medicine, 1909; died in the Altoona Hospital April 15, aged 60, of carcinoma of the uterus.

Maximilian Malina, Chicago; Chicago College of Medicine and Surgery, 1911; on the staffs of the Walther Memorial and Norwegian American hospitals; died May 23, aged 63, of coronary insufficiency and chronic myocarditis.

Frank Lynn McCready ⊕ Sewickley, Pa.; University and Bellevue Hospital Medical College, New York, 1899; past president of the board of health of Sewickley; commissioned in the medical section of aerial photography, with rank of captain, during World War I; on the staff of the Sewickley Valley Hospital; died May 16, aged 71, of pneumonia.

Marvin Alford McDowell ⊕ Logansport, Ind.; Indiana University School of Medicine, Indianapolis, 1911; served during World War I; member of the American Psychiatric Association; on the staff of the Logansport State Hospital; died May 21, aged 66, of cerebral thrombosis.

Sherwin E. Mella ⊕ Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1919; member of the American Academy of Dermatology and Syphilology; instructor in dermatology at the University of Kansas School of Medicine, Kansas City, Kan.; on the staffs of Menorah Hospital and St. Luke's Hospital, where he died May 18, aged 49, of coronary disease.

Henry Estes Merriam, Ithaca, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1894; retired member of the Medical Society of the State of New York; member of the American Medical Association; past president of the Tompkins County Medical Society; served during World War I; died in the Clifton Springs (N. Y.) Sanitarium June 25, aged 76, of cerebral hemorrhage.

Samuel Gibbs Milliken, Houston, Texas; University of Texas School of Medicine, Galveston, 1922; formerly adjunct professor of pathology at his alma mater; interned at the Peter Bent Brigham Hospital in Boston; served overseas during World War I; died March 23, aged 49, of bilateral pulmonary tuberculosis and toxic myocarditis.

Ben Parmenter, Mount Carmel, Ill.; Barnes Medical College, St. Louis, 1909; died May 10, aged 63, of heart disease.

Wallace Bernard Phillips, Gary, W. Va.; John A. Creighton Medical College, Omaha, 1916; died May 20, aged 52, of acute dilatation of the heart.

Walter Jewett Pinkerton ⊕ Ramsay, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; formerly mayor of Bessemer; physician for the Castile Mining Company; served on the staff of the Grand View Hospital in Ironwood; died May 9, aged 72, of carcinoma of the stomach.

William James Pinkerton ⊕ Omaha; Omaha Medical College, 1898; served during World War I; died in the Clarkson Memorial Hospital, April 15, aged 74, of bronchopneumonia and carcinoma of the urinary bladder.

William Warren Quinton ⊕ Major, U. S. Army, retired, Santa Barbara, Calif.; Columbia University College of Physicians and Surgeons, New York, 1892; entered the army as a first lieutenant on Oct. 26, 1893 and retired with rank of major in 1909 for disability in line of duty; died in St. Francis Hospital July 18, 1943, aged 73, of coronary sclerosis and arterial hypertension.

Emanuel M. Radlow, Cold Spring, N. Y.; Albertus-Universität Medizinische Fakultät, Königsberg, Prussia, Germany, 1901; died April 14, aged 68, of cerebral hemorrhage and chronic arteriosclerosis.

Sol E. Ravitz, Chicago; University of Nebraska College of Medicine, Omaha, 1920; clinical associate in dermatology and syphilology and secretary of the department, Loyola University School of Medicine; a member of the out-patient department of the dispensary of the Mercy Hospital; died May 19, aged 48, of coronary thrombosis.

Dean Stelle Rising ⊕ Kansas City, Mo.; University Medical College of Kansas City, Mo., 1910; on the staffs of St. Vincent's Hospital and St. Joseph's Hospital, where he died May 12, aged 61, of coronary thrombosis.

Martin M. Ritter, Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1892; served as chief of staff and at one time vice president of the staff of the Columbus Hospital in Chicago; died June 12, aged 82, of myocarditis.

Abraham Rosenberg ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1905; died May 26, aged 63, of heart disease.

Albie Jens Rosholt, La Crosse, Wis.; Rush Medical College, Chicago, 1908; member of the American Medical Association; secretary of the La Crosse County Medical Society; served during World War I; at one time county physician; for many years on the staffs of the La Crosse and St. Francis hospitals; formerly on the staff of the La Crosse Lutheran Hospital; director and at one time president of the State Bank of Rosholt; died in Sparta May 16, aged 66, of coronary occlusion.

Edwin Ross, St. Helens, Ore.; University of Oregon Medical School, Portland, 1894; for many years city health officer; served as bank president; died March 29, aged 80.

William F. Schaare ⊕ Chicago; College of Medicine and Surgery (Physio-Medical), Chicago, 1902; veteran of the Spanish-American War; served as national president of the 7th Army Corps Veterans' Association; died in River Forest June 19, aged 69, of cerebral hemorrhage.

J. H. Alfred Schulz, Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; died May 11, aged 74, of myocardial degeneration.

Henry Franklin Slifer, North Wales, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1876; at one time president of the Montgomery County Medical Society; emeritus professor of physiology at the Temple University School of Medicine, Philadelphia; at one time professor of physiology at the North Wales Academy and the Medico-Chirurgical College of Philadelphia; for many years a member of the school board; died April 2, aged 92.

Edwin Kirby Smith, McMinnville, Tenn.; George Washington University School of Medicine, Washington, D. C., 1927; member of the Medical Society of the District of Columbia and the American Medical Association; interned at the Garfield Memorial Hospital and the Children's Hospital in Washington, D. C.; served a residency at the Children's Hospital in Cincinnati; died June 21, aged 46, of heart disease.

Caleb S. Stone Sr., Seattle; Louisville (Ky.) Medical College, 1883; member of the American Medical Association and the Idaho State Medical Association; died May 31, aged 88, of uremia.

Edwin Wilfred Stubbs, Aurora, Ill.; Marion-Sims College of Medicine, St. Louis, 1897; served as county physician; examining physician for the draft board during World War I; died in the Copley Hospital May 26, aged 81, of coronary occlusion and generalized arteriosclerosis.

Ross Adams Switzer, McHenry, Miss.; Chattanooga (Tenn.) Medical College, 1902; member of the board of supervisors of Stone County for twenty-eight years, serving as president of the board at the time of his death; died May 1, aged 69.

Toyohiko Campbell Takami ⊕ Brooklyn; Cornell University Medical College, New York, 1906; on the staffs of the Cumberland and Prospect Heights hospitals; member of the board of the Long Island Biological Association of Cold Spring Harbor; died May 17, aged 70, of pneumonia.

Thomas Franklin Taylor, Monteagle, Tenn.; Vanderbilt University School of Medicine, Nashville, 1897; member of the American Medical Association; secretary of the Grundy County Medical Society; died April 24, aged 75, of carcinoma of the liver.

Thomas G. Taylor, Leaksville, N. C.; Kentucky School of Medicine, Louisville, 1877; served as mayor of Leaksville; died in the Leaksville General Hospital April 17, aged 88, of cerebral hemorrhage.

Walter Leon Teaby, Monterey, Calif.; College of Physicians and Surgeons of San Francisco, 1903; member of the American Medical Association; formerly associated with the U. S. Public Health Service; served as city councilman and as mayor of Monterey; died May 1, aged 73.

Joseph Abbott Thissell, Tupper Lake, N. Y.; Harvard Medical School, Boston, 1885; an organizer of the Tupper Lake Water Company, serving as first treasurer and president of that firm; instrumental in organizing the Tupper Lake National Bank and served as one of its first directors; for many years surgeon for the New York Central Railroad; served as medical examiner for the New York Life, Mutual Life and Prudential Insurance companies; died in the Mercy General Hospital May 13, aged 86, of pneumonia.

William Thomas Thorn, Marked Tree, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; died in the Baptist Hospital, Memphis, Tenn., May 1, aged 72, of heart disease.

Edward Vincent Tolan ⊕ Pottsville, Pa.; Jefferson Medical College of Philadelphia, 1929; interned at Misericordia Hospital and served as resident physician at St. Christopher's Hospital for Children, both in Philadelphia; on the staffs of the Good Samaritan and Pottsville hospitals; died May 15, aged 40, of coronary occlusion.

Theodore Henry Trappe, New Athens, Ill.; St. Louis College of Physicians and Surgeons, 1910; member of the American Medical Association; died June 13, aged 66, of coronary disease.

Lloyd Herman Van Slyke, Black Earth, Wis.; Chicago College of Medicine and Surgery, 1916; served with a field hospital at Chateau Thierry, St. Mihiel and the Argonne in World War I; died in the Veterans Administration Facility, Wood, March 24, aged 53, of carcinoma.

William Conrad Wessel, Hermann, Mo.; Marion-Sims College of Medicine, St. Louis, 1899; served as local surgeon for the Missouri Pacific Railroad; died in State Hospital number 1, Fulton, April 11, aged 69, of cerebral hemorrhage.

William Kerr West ⊕ Hinsdale, Ill.; Detroit College of Medicine, 1889; member of the House of Delegates of the American Medical Association in 1905; fellow of the American College of Surgeons; for many years surgeon in the mines of the Copper Range Company in Painesdale, Mich.; on the staff of the Hinsdale Sanitarium and Hospital; died June 16, aged 79, of carcinoma of the prostate and cecum.

Allan Sinclair White, Racine, Wis.; Michigan College of Medicine and Surgery, Detroit, 1899; fellow of the American College of Surgeons; served on the staff of St. Joseph's Hospital in Rice Lake; died in June, aged 69.

Henry Bristol Wideman, Nevada, Ohio; University of Wooster Medical Department, Cleveland, 1893; member of the American Medical Association; served as coroner of Wyandot County; died April 5, aged 75, of heart disease.

John Lawrence Widmyer, Primos, Pa.; Medico-Chirurgical College of Philadelphia, 1901; member of the American Medical Association; on the staff of the Delaware County Hospital, Drexel Hill; died in the Fitzgerald Mercy Hospital, Lansdowne, April 10, aged 67, of coronary occlusion.

William Hall Wynne ⊕ Birmingham, Ala.; Birmingham Medical College, 1897; on the staffs of the Jefferson and Baptist hospitals; died May 28, aged 72, of heart disease.

LIEUT. ANTHONY SALVATORE GRECO
M. C., A. U. S., 1917-1944

LIEUT. THOMAS ROBERT TURINO
(MC), U.S.N.R., 1906-1944

CAPT. EDWARD L. YOUNG III
M. C., A. U. S., 1914-1945

KILLED IN ACTION

Anthony Salvatore Greco, Omaha; Creighton University School of Medicine, Omaha, 1941; interned at Creighton Memorial St. Joseph's Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 1, 1942; killed in action in Italy June 22, 1944, aged 27.

Thomas Robert Turino ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1931; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; diplomate of the National Board of Medical Examiners; interned at the Brooklyn Hospital, where he served as associate gynecologist and obstetrician; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve on Aug. 20, 1942; reported by the Navy as missing in action on July 18, 1943; presumptive date of death in the Pacific area July 19, 1944, aged 37.

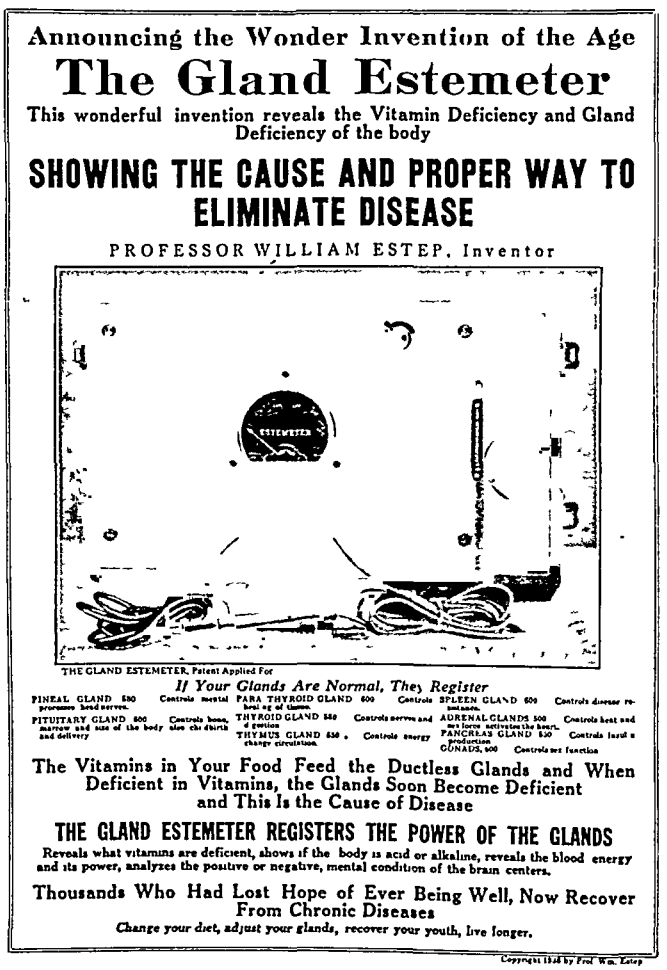
Edward Lorraine Young III, Brookline, Mass.; Harvard Medical School, Boston, 1941; member of the American Medical Association; diplomate of the National Board of Medical Examiners; interned at the Massachusetts General Hospital, Boston; entered the medical corps, Army of the United States, as a first lieutenant on April 27, 1943; began active duty on May 8, 1943; promoted to captain; went overseas in March 1944, serving at a field hospital in the front line; killed in action in Germany March 24, aged 30.

Bureau of Investigation

ESTEP RUNS INTO GRIEF

"Mahatma" Apprehended in Mexico for Murder

In Memphis, where William Estep, also known as "Mahatma" and "Professor," has been styling himself "director" of the high-sounding Memphis Research Clinic, newspapers have reported that he was recently arrested in Mexico and held by Laredo, Texas, authorities for return to the Tennessee city to face a charge of second degree murder.



The earlier chapters of Estep's checkered career were last reviewed in this department of THE JOURNAL, Jan. 21, 1939, page 200. Briefly summarized, the article traced the "Mahatma's" career from 1930, when this Bureau first heard of him. In that year a Better Business Bureau bulletin reported that "Prof. Wm. E. Estep, proponent of 'Super Mind Science,' played Chicago in April. With the aid of a trained monkey and complimentary press notices, Estep attracted numerous followers to his 'free' lectures." Further, he claimed at that time to have degrees from two universities, whose existence investigation failed to substantiate. The bulletin further reported that a "Rev. Wm. Estep" had a record in Los Angeles, where he had been arrested in November 1923, following a raid on his "Spiritualistic Temple" and had been fined $250 when found guilty of obtaining money by false pretenses; that a follower and convert of Estep stated that the "Mahatma" took in $40,000 through his Chicago meetings, and that a plumber's assistant who had signed up for Estep's "Success Course" in Chicago, on the promise that it would make him a successful business man, had caused Estep's arrest when the course failed to touch on business. The case was dismissed in court when Estep made restitution.

Another bulletin from the same source reported shortly thereafter that Estep was accused of racketeering in his home town, Detroit, together with his wife and three other persons, in selling memberships at $40, including a supposed life insurance benefit to members under 50, in an alleged fraternity, the "Order of Temple Builders."

THE JOURNAL article showed that Estep's advertising represented that he was "the only American to ever qualify to become a mahatma. He was sponsored by Swami Ram Karan Dass, India's most noted Master Prophet"

Also there was the report from Kansas City, Mo., that Estep had been selling literature published by the Positive Christianity Publications, Washington, D. C., and taking $100 fees for courses leading to a degree that he called MS.D. (Doctor of Metaphysics), and that in 1938 he had incorporated a concern in Kansas City known as the Gland Estemeter Corporation, which, according to a newspaper notice, was, among other things, "to build, equip and maintain institutions for the treatment and care of the sick; to manufacture and sell Prof. Estep's 'Gland Estemeter' (patent applied for) . . . to deal in health foods; to deal in and dispose of such real and personal property and securities as are necessary to the conduct of said business . . ." THE JOURNAL article went on to state that an advertising folder on the Estemeter "indicates such blatant ignorance that it is astounding that any one would ever bother putting it into type. Still harder to believe is the idea that it could induce the prospect to purchase one of these machines, the reported cost of which is $250 (price not mentioned in folder)." The device was supposed to register various ductless glands according to "points" which would indicate their condition, and in accompanying literature Estep referred to the "wonderful" discovery of Dr. Albert Abrams, of whose preposterous quackery Estep was a disciple.

In June 1941 the Federal Trade Commission reported that its findings were that the Estemeter is incapable of detecting or disclosing improper or abnormal functioning of the glands and possesses no value in diagnosing diseases or conditions of the body, Estep's claims notwithstanding. The Commission therefore ordered Estep and his concern to discontinue the misrepresentations that had been made for the device. This case was briefly abstracted in THE JOURNAL Jan. 17, 1942, page 246.

This "Wonder Invention of the Age" was Estep's stock in trade a few years ago.

In November 1942 newspapers reported that Estep and some associates had been arrested in Pensacola, Fla., following indictment charging mail fraud and violation of the Securities Act of 1933. The charges were said to have followed the sale of stock in Estep's Rainbo and Trinity Gold Mines. In this connection it was brought out that Estep allegedly had represented that one of the followers of his Church of Positive Christianity and Supermind Science Cult had seen a "vision" that revealed a mountain of gold in Utah, which Estep proceeded to exploit. According to the Pensacola (Fla.) *News* of Sept. 6, 1944 Estep was found guilty in this case in December 1942 but, on appeal, his conviction was reversed.

In April 1945 a Memphis newspaper reported that William Estep, who had been enjoined from the practice of medicine in his Vita-Ray Clinic at Pensacola, Fla., had gone to Tennessee and opened the "Memphis Research Clinic," which he advertised as an "X-ray clinic for chronic diseases." The Memphis paper further reported that Estep's Florida license as a naturopathic physician had been revoked Nov. 23, 1942 by the Florida State Board of Medical Examiners, on the ground that it had been obtained fraudulently from the late Dr. George A. Munch, secretary of the old Eclectic Board, who served a sentence in federal prison for using the mails to defraud. It appears, however, that Estep entered an appeal before the Florida Supreme Court and that this is still pending.

In his latest escapade, according to a Memphis paper, Estep fled that place for Kansas City, Mo., whence he made his way to Mexico and was apprehended on May 31 in Monterrey. He was charged with murder in the second degree, resulting from the unlawful administration of certain drugs to a Negro woman, which resulted in her death. After the return of the first indict-

ment, according to the report, he fled from the jurisdiction of the court, forfeiting a bond of $1,500. While in Kansas City, it is said, he gave lectures on "health foods" until May 1, when he made a "quick exit," leaving a hotel bill unpaid. It is reported that when Estep came to Memphis he purchased property and recorded a Tennessee license as a "naturopathic physician" on January 15, but that after his clashes with the law the Tennessee State Board of Naturopathic Examiners had revoked his license.

These are the "Mahatma's" present difficulties. Will he see the light and abandon his long career in quackery? Probably not, unless some agency of government places him where any amount of mind science fails to return the cash of the credulous.

Correspondence

AN AMERICAN MEDICAL ASSOCIATION FILM SERVICE

To the Editor:—In five recent articles in American and British journals, various authors have called attention to the important developments in health teaching and medical training films which are bound to occur in the postwar period.

REASONS FOR SLOW DEVELOPMENT IN PAST

The motion picture has been slow in establishing a place for itself in the field of medical teaching. In the first place, this device with its limited eye and ear approach has had to compete with bedside teaching and laboratory teaching with their multiplicity of approaches. In the second place, medical teachers have made such extended use of actual specimens, photographs, teaching charts, lantern slides, cross sections and models in illustrating their lectures and have illustrated their textbooks and articles so lavishly that the need for the motion picture has not been apparent.

In the field of medicine, therefore, the use of the motion picture has had to be selective and with due deference to other methods of education, which in their place have proved to be more thorough and more effective. Some of the considerations on which selection has been based in applying the motion picture to medical and health teaching follow:

1. Films may often be used to advantage in introducing a new subject to a group. We may think of an orientation film of this type as utilizing the principle of taking a traveler up on the hilltop to give him an overall view and sense of direction before he enters the forest below and attempts to make his way through the trackless waste. The film so used has a real place in our medical schools.

2. Films may be helpful in demonstrating new principles, new technics and new apparatus to groups that are already familiar with the basic problems in the particular field. Used in this way as a means of keeping busy practitioners in touch with the latest developments in medicine, the film would appear to offer very attractive possibilities.

3. Where technicians must be trained for a specific task with a minimum of basic scientific training in order to save time and expense, films can often be made to do for such workers what would otherwise require extensive courses. For example, a film showing how carelessness with regard to aseptic technic in the operating room can cause postoperative infection may do for the Navy hospital corpsman much that a course in bacteriology does for the doctor in creating a respect for aseptic technic.

4. In the fields of school health education, college health education and public health condition, where the need is not for detailed knowledge but rather for a general, overall knowledge of hygiene, preventive medicine and public health in order to improve living habits and make for intelligent support of public health measures, motion pictures have an important part to play.

PROBABILITY OF RAPID DEVELOPMENT IN FUTURE

The experience of both the Army and the Navy in training medical technicians to meet their military duties, in preparing medical personnel for combating tropical diseases new to them and in warning line personnel as to the necessary precautions they must take if they are to avoid the diseases of the occupied areas has proved beyond any shadow of doubt the value of medical training and health teaching films. So convincing has been the demonstration that it is a generally accepted fact that the postwar period will see a tremendous increase in the production of health teaching and medical training films.

It is obvious, however, that unless a central clearing house for this type of film is established there is bound to be wasteful duplication of effort, poorly planned production and, in many instances, even complete misapplication of the film approach.

THE URGENT NEED

There is an immediate and urgent need for the establishment of a central film service for health teaching and medical training films which shall review, describe and catalogue (but not evaluate) all films already produced in these fields, list all medical films in the process of production and act as requesting, sponsoring and supervising authority for the production of medical films.

WHO SHOULD MEET THE NEED?

It is thinkable that this centralized film service for health teaching and medical training films should be set up (*a*) as an educational activity and therefore a part of the National Education Association; (*b*) as a scientific activity and therefore a part of the American Association for the Advancement of Science, (*c*) as a medical activity and therefore a part of the American Medical Association, (*d*) as a public health activity and therefore a part of the American Public Health Association or the U. S. Public Health Service and (*e*) as a motion picture production activity and therefore a function of the entertainment film industry or of the industrial film producers.

In considering these various groups as sponsors for a medical film service, the following facts should be given careful consideration:

Though educational theory and technic enter importantly into the production of both health teaching and medical training films, the medical subject matter rather than the educational approach would seem to be the dominating factor; both education and science cover such wide fields that practical organization and comprehensive coverage would appear difficult, if not impossible, under the sponsorship of either of these widely flung groups; the American Public Health Association and the U. S. Public Health Service are concerned almost entirely with preventive medicine and would therefore have little interest in the medical training films, though great interest in the health teaching films; there is but little profit in the production of medical films, so that if producers of entertainment or industrial films enter the medical film field they will probably do so only in a half-hearted way and as a minor part of their interest; whoever sponsors a central medical film service should have funds and facilities sufficient to provide films that will meet the needs of physicians, nurses and medical technicians both in training and in service.

In my judgment the American Medical Association is in the best position to serve as the central agency for the promotion and utilization of health teaching and medical training films.

D. F. Smiley, Lieutenant Commander (MC), U.S.N.R.

The opinions and views set forth in this communication are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

THE PHYSICIAN AND THE SELECTIVE SERVICE SYSTEM

To the Editor:—In retiring from Selective Service, after serving as chief of the Medical Division during the last four and one-half years, I have received literally dozens of letters complimenting us on what has been accomplished. Most of these letters, I note, came from physicians. In reading them and in thinking over the situation, it seems to me that the shoe really should be placed on the other foot. Hence I am writing to express the gratitude of the Medical Division of Selective Service to the 35,000 doctors and 10,000 dentists who have contributed so liberally of their time, effort and skill in handling the medical problems of the registrants.

No other group of people in the nation have given more liberally of themselves in the war than have these professional people. That was the opinion expressed by the late President Roosevelt at one of his wartime conferences.

The Medical Division of Selective Service in National Headquarters in Washington has enjoyed the complete support of the director, Major Gen. Lewis B. Hershey. It has had also the strong support and superlative leadership from the three Surgeons General of the Army, Navy and Public Health Service, from all the state headquarters and especially from all the state medical officers. The physicians attached to the 6,443 local boards, the consultants on the 660 medical advisory boards supplied all the demands made on them. They met fully and completely the nation's needs in the procurement of manpower for the fighting forces.

Such service should not be taken for granted nor should it be passed over without acknowledgment. Medicine has done a grand job in this war in Selective Service as well as in the Medical Corps of the Army, Navy and Public Health Service.

In leaving Selective Service I wish to express to all the civilian physicians and dentists in the Selective Service System my personal appreciation and that of the Medical Division at National Headquarters for the wholehearted service they have rendered throughout the last four and one-half years.

L. G. ROWNTREE, M.D.
Selective Service System,
Washington, D. C.

FEMALE INFERTILITY

To the Editor:—The communication from Dr. Roy J. Hefferman (THE JOURNAL, June 23) attempting to add another etiologic factor to the subject of female infertility has failed to furnish a rational biologic relationship between "voluntary sterility" and the direct impairment of the human reproductive organs. His warning against the use of contraceptives by newly married couples may be of considerable significance from the point of view of dogmatic theology, for sentimental justification or for some indefinite sociologic reasons. However, it lacks the establishment of a definite physiologic explanation for the alleged causation of a pathologic condition of the pelvic organs.

The pelvic pathologic conditions such as ovarian cysts, fibroids, endocervicitis and endometriosis enumerated by the correspondent are conditions present in sterile and in fertile females. This has been the observation of numerous gynecologists. The mere finding of pelvic pathologic conditions in women who have practiced "voluntary sterility" does not, logically or scientifically, justify the conclusion that this pathologic condition was the effect of the contraceptive practice. The assertion that "planned sterility by the use of contraceptives" constitutes a primary etiologic factor in the causation of pelvic pathologic conditions, with subsequent permanent sterility, or female infertility, is not borne out by clinical observation and is contrary to the biologic concept of organic changes.

DAVID DEUTSCHMAN, M.D., New York.

EPIDEMIC PLEURODYNIA

To the Editor:—I read with great interest the editorial in THE JOURNAL June 16 on the subject of epidemic pleurodynia. Reference is made to the apparent lack of microscopic studies of the affected tissues in these patients. In the late summer of 1935 I had an opportunity to see several of these patients at the Cincinnati General Hospital. One of these patients, a woman intern, had a small section of the latissimus dorsi muscle removed in the surgical service of the late Dr. Mont R. Reid. Microscopic study of this apparently affected muscle did not show any morphologic changes. These findings were reported in the *American Journal of the Medical Sciences* **191**:673 (May) 1936. At that time this appeared to be the first such study which had been made.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, July 21, page 900.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: January. Sec., Dr. B. R. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARKANSAS:* *Medical.* Little Rock, Sept. 20-21. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral.* Los Angeles, Aug. 11. *Written.* Los Angeles, Aug. 13-16. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

DISTRICT OF COLUMBIA:* *Reciprocity.* Washington, Sept. 10. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

ILLINOIS: Chicago, Oct. 9-11. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

LOUISIANA: New Orlears, Aug. 16-18. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

MARYLAND: *Homeopathic.* Baltimore, Dec. 11-12. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MONTANA: Helena, Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEVADA: *Reciprocity.* Carson City, Aug. 6. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, Oct. 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Oct. 1-4. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

WISCONSIN:* Madison, Jan. 8-10. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, Oct. 1-2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, Sept. 5-6. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Oct. 13. Address State Board of Healing Arts, 250 Church St., New Haven 10.

DISTRICT OF COLUMBIA: Washington, Oct. 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: DeLand, Nov. 3. Sec., Dr. J. F. Conn, Box 655, DeLand.

MICHIGAN: Ann Arbor and Detroit, Oct. 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

MINNESOTA: Minneapolis, Oct. 2-3. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

NEBRASKA: Omaha, Oct. 2-3. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

RHODE ISLAND: Providence, Aug. 15. Chief, Division of Examiners, Mr. Thomas Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: December. Sec., Dr. J. D. Alway, Aberdeen.

TENNESSEE: Memphis, Sept. 24-25. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: Madison, Sept. 22. Sec., Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Harrison Narcotic Drug Act: Illegal Issuance by Physician of Narcotic Prescriptions to Addict.—An indictment was returned to the district court of the United States, eastern district, New York, charging in six counts that Abdallah, who was licensed to practice medicine in New York, had violated a section of the federal narcotic drug laws [26 U. S. C. A. Internal Revenue Code, section 2554 (a)] by selling morphine to an addict without a written order on a form issued for that purpose by the Secretary of the Treasury. At the trial the government presented evidence that a stated agent of the United States Narcotic Squad made several trips to the vicinity of Abdallah's office with a drug addict; that on each occasion the agent searched the addict thoroughly, found nothing on him, and then gave him money; that each time the addict visited Abdallah and returned to the agent with a prescription or prescriptions for morphine, in combination with ephedrine, which prescriptions were promptly turned over to the agent; and that the agent on each occasion then drove the addict to the vicinity of a certain pharmacy, where the prescriptions were filled. The amount of the prescriptions varied with the amount of money given by the agent to the addict. There were six of these transactions from March 10 to March 30, 1943, and each transaction was the subject of a different count of the indictment. On the last three transactions Abdallah gave the addict several postdated prescriptions. There was evidence that Abdallha examined the addict at least once, and that the addict complained to him of asthma, that during the course of the examination the physician made the addict strip to the waist, and that the addict had needle marks on his arm, which the physician must have noticed and which ought to have put him on guard as to the addiction of his purported patient. The addict testified that the physician accused him of being an addict but nevertheless issued the prescription; and that the physician warned him not to fill the prescriptions with one druggist, not to carry the bottles on his person, and to tear the labels off the bottles and that the physician urged him to supply a friend in whose name future prescriptions could be made out. There was further evidence that the addict never had asthma and that the physician was well aware that morphine is not a specific remedy and should be used only in extreme cases to quiet a person with loss of sleep and then only with great caution. The evidence was undisputed that the addict obtained twelve prescriptions for morphine from the physician on six visits within a period of twenty days. On the addict's last visit to the physician he was given marked money, which the physician turned over to narcotic agents when they subsequently arrested him. After his arrest he could not produce any record showing the names of patients for whom he had prescribed narcotics. In lieu of the records he attempted to introduce at the trial his diary, but this showed discrepancies from the prescriptions presented in evidence by the government. The jury found the physician guilty on the three counts of the indictment covering the last three transactions between the physician and the addict in which the physician had given the addict several postdated prescriptions. The jury found the physician not guilty with respect to the first three counts, with respect to transactions in which single prescriptions had been issued to the addict. The physician then appealed to the circuit court of appeals, second circuit.

The government contended, in line with the holding by the circuit court of appeals, second circuit, in *United States* v. *Lindenfeld*, 142 F. (2d) 829, certiorari denied 65 S. Ct. 89, that Abdallah by his course of conduct had removed himself from the protection of a section of the federal narcotic laws [26 U. S. C. A. Internal Revenue Code, section 2554 (c) (1)], which excepts from the general prohibitions of the law distribution of narcotic drugs "by a physician . . . in the course of his professional practice only." Abdallah urged the court to reconsider its holding in the Lindenfeld case that the question as to whether the defendant comes within the exception was one of fact as to his good faith, for the jury to decide, and contended that there must be a consent or conspiracy between the physician and the druggist filling the prescription in order to render the physician's acts unlawful. The court, however, refused to reconsider its prior decision in the Lindenfeld case and in effect sustained the contention of the government and refused to entertain Abdallah's contention.

From the evidence, continued the court, the jury in the trial court was clearly entitled to infer Abdallah's bad faith. As a matter of fact, the jury seems to have exercised discrimination in its verdict, giving Abdallah the benefit of all possible doubt on the first three counts of the indictment, which charged the illegal issuance of a single prescription at a time, while finding him guilty on the last three counts, charging the issuance of several postdated prescriptions at a time, where bad faith seems undeniable. The physician contended, however, that the government failed to prove the filling of the prescriptions by a druggist, which he argued was a necessary element of the sale of narcotics as here charged. The evidence, answered the court, is contradictory as to whether or not the druggist filled the prescriptions according to directions, including ephedrine sulfate and milk sugar, or as to whether or not the addict obtained pure morphine sulfate instead. But as long as acquisition of the opiate as a result of the prescription is shown, we think it cannot excuse the wrongful act of the physician that the druggist did not fulfil the directions precisely or even took advantage of the opportunity to expand the illegal traffic. In either event the prescription is the instrument leading to the completion of the crime. Obviously the interest of the druggist is to obtain a seemingly legitimate basis for rapid depletion of his morphine stock and the physician has furnished him that opportunity by his prescription, whether it is followed to the letter or not. With its purpose thus fulfilled, the crime is complete.

The physician urged, however, that the crime here charged was completed through the agency of a decoy and detective, whose acts cannot be imputed to him so as to render him guilty of the offense charged, citing *People* v. *Lanzit*, 70 Cal. App. 498, 233 P. 816; *Dalton* v. *State*, 113 Ga. 1037, 39 S. E. 468; *State* v. *Decker*, 321 Mo. 1163, 14 S. W. (2d) 617; *Williams* v. *Georgia*, 55 Ga. 391; and *DeMayo* v. *United States*, 8 Cir., 32 F. (2d) 472. We need not consider, said the court, how far the principle urged by Abdallah may be soundly pressed, since all that the cases cited by the physician stand for is that acts done by a detective in building up the commission of an offense cannot be imputed to a defendant. They do not determine or limit the participants in steps leading to the completion of the offense once it is shown to have been committed. Here the crucial act was committed once the prescriptions were issued. The filling of the prescriptions merely carries the act to the final point where it becomes punishable as the crime in question. Thus the administering of poison may not constitute murder until the victim perishes; but once this occurs the act of administering constitutes the offense. The crucial act of the issuance of the prescriptions was one not performed by the detective or the addict, but by the defendant of his own volition and intent.

This holding, continued the court, disposes of an objection by the physician to his conviction on the last count for issuing prescriptions which were not filled until after his arrest. Nor do we find merit in a further contention by the physician as to entrapment. As was said in *United States* v. *Lindenfeld*, supra:

> Entrapment exists only when the government agents induce and originate the criminal intent of a defendant; there is none where the criminal intent is already present, and the agents merely afford the opportunity for the commission of a crime.

Despite the physician's claim of having been duped by the addict, the instructions given by the court to the jury and the jury's verdict negative the existence of the defense.

Finally, the defendant objected to the admission in evidence of 115 prescriptions for narcotics issued by him and found on a spot check of drug stores in the neighborhood of his office. These prescriptions, said the court, were competent and relevant evidence on the question of the physician's good faith and as such they are not barred, even if they tended to establish offenses other than the one with which the defendant was charged. The judgment of conviction was accordingly affirmed. —*United States v. Abdallah, 149 F. (2d) 219 (1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Teratoma of Liver in an Infant. P. H. Hartz and A. van der Sar. —p. 159.

Human Chronic Toxoplasmosis.—The literature reveals that 13 cases of toxoplasma infection have been diagnosed at necropsy, and 3 clinical cases have been diagnosed by recovery of the parasites from cerebrospinal fluid. Weinman, in a study of immunity in experimental toxoplasmosis, found that chronic toxoplasmosis in animals produced a different picture from the acute disease. Human chronic toxoplasmosis has not been demonstrated. While reviewing the necropsy material on sickle cell anemia, Tomlinson found an instance of chronic toxoplasmosis in a British West Indian Negro girl aged 10 years 8 months, who died of sickle cell anemia in the Canal Zone and who had no symptoms referable to toxoplasma infection. The case therefore represents the first reported case of chronic, asymptomatic human toxoplasmosis. Toxoplasma parasites were found in pseudocysts throughout the brain and in aggregates within myocardial fibers. They were not accompanied by inflammatory changes or necrosis.

Fatality Due to Transfusion of Unpooled Plasma.—Alberton reports a fatality following the use of unpooled plasma in which the cause of death was proved to be hemolytic reaction due to blood group incompatibility. The patient was a woman aged 77 who underwent a gastric resection for carcinoma of the stomach. A blood transfusion had to be stopped after 150 cc. of blood had been given. A transfusion of plasma was started two days later, but after only 100 cc. had been given the patient complained of severe lumbar pain. The patient rapidly became ashen gray and cyanotic. The transfusion was stopped with the first symptoms, and supportive measures were started. She died several hours later. The unpooled incompatible plasma saline mixture which had been infused was found to contain anti-A agglutinins active in a dilution of 1:2,048 (± 1:4,096). The patient had group A cells of average sensitivity. On the basis of this report the theoretical objections to the use of unpooled plasma are proved to have factual foundation. Unpooled plasma should be given only to homologous type recipients when the titer of agglutinins is not known.

Differential Diagnosis Between Fetal and Maternal Heart Rate. M. Berlind.—p. 703.

Treatment of Cervicitis.—Findley's observations are based on 240 cases of chronic cervicitis treated by the three generally accepted methods of electrosurgery: actual or nasal tip cauterization, electrocoagulation and conization. Microscopic studies were made before treatment and after healing was clinically complete. The average rates of healing were the same with all three methods. The percentage of satisfactory results was greatest after electrocoagulation, second after conization and least following cauterization. There was little difference between coagulation and conization in the terminal microscopic picture. Fibrous tissue reaction was low in both procedures, although slightly greater following cauterization. Complications most commonly encountered were hemorrhage, stenosis and pyometra and were most frequently seen following conization. Hemorrhage usually occurs from the tenth to the fifteenth day at the time of separation of the slough. Stenosis, with resultant pyometra may be largely prevented by repeated dilation of the cervical canal. Carcinoma was discovered in 2 unsuspected cases out of 240 examined. Internal menstrual tampons were found to interfere with proper healing. Their use is to be condemned.

Gangrene of Extremity in Newborn Child.—Steiner observed gangrene of the upper left extremity in an infant born fifty hours after rupture of the membranes and two hours after the onset of labor. At delivery the affected extremity was found prolapsed between the cranium and the bony pelvis. Conservative therapy was ineffective and amputation was necessary on the eleventh day of life. To date, 42 similar cases have been reported in the literature. Trauma is the most likely cause of the condition.

Toxoplasmosis Mistaken for Histoplasmosis in a Cat. H. D. Melenry. —p. 163.

Tropical Eosinophilia and Microfilaria.—Van der Sar and Hartz report 3 cases of tropical eosinophilia. In 1 case microfilariae could be demonstrated in the eosinophilic abscesses and infiltrate in the enlarged axillary lymph nodes. The symptoms disappeared after treatment with oxophenarsine hydrochloride. In a second case there was myeloid metaplasia of an axillary lymph node, consisting almost exclusively of eosinophilic myelocytes. In a fourth case which came to necropsy after an automobile accident hypereosinophilia of the blood and the liver was present; the spleen was enlarged and the subcapsular pulp contained enormous numbers of eosinophilic leukocytes and microfilariae. Eosinophilia was also found in the members of the family. In the last twenty-five years numerous publications have appeared concerning the occurrence of a hyperleukocytosis with hypereosinophilia, concurring clinically with enlargement of superficial lymph nodes, occasionally enlarged spleen and attacks of asthmatic bronchitis. Roentgenologically small bronchopneumonic foci could be demonstrated in some cases. Reports by Giffin in 1919, Aubertin and Giroux in 1921, Armand-Delille and Pierredon in 1927, Valledor and others in Cuba in 1939 and by Myers and Kouwenaar in the Netherlands East Indies in 1939 demonstrated the relationship between tropical eosinophilia and filariasis. The observations of the authors have demonstrated the relationship between tropical eosinophilia and filariasis and have reopened the discussion of the treatment of filariasis with arsenic.

Agglutinins and Autohemagglutinins in Tropical Diseases.—Heterophile agglutinin and cold autohemagglutinin titers were determined by Dammin and Weller in 123 cases of schistosomiasis, 104 cases of filariasis, 40 untreated cases of malaria and 18 cases of leprosy. In schistosomiasis, 4.9 per cent had heterophile agglutinin titers over 1:32, in filariasis 13 per cent had titers above 1:32, and of the malaria cases 5 per cent had titers above 1:32; in no case was the titer higher than 1:128. In the small group of blood specimens from patients with leprosy 4 showed a heterophile agglutinin titer of 1:128. Of 12 patients with malaria given quinine, 9 had a titer of 1:32 or lower and 3 a titer of 1:64. In 285 blood specimens, cold autohemagglutinins in a titer of 1:10 or higher could not be demonstrated in 279, or 97 per cent. The data indicate that heterophile antibody titers of clinical significance are not frequent in schistosomiasis, filariasis and malaria. From the results obtained no conclusions may be reached as to whether Wuchereria bancrofti and Schistosomum mansoni contain a heterophile antigen which at some stage in the disease process might produce significant antibody titers. It is possible that a titer of 1:64 in the 13 filariasis plasma specimens might represent such a stage of activity.

*Cutaneous Diphtheria as Military Problem: Review of Literature, with Report of Case. M. H. Saffron.—p. 337.

Cutaneous and Articular Manifestations in Lymphogranuloma Venereum.—The articular manifestations of lymphogranuloma venereum fall into one of three clinical categories: 1. Arthralgia with migratory pains in the joints, usually fleeting and without objective evidence of articular disease, is of common occurrence in the early weeks of the infection. 2. There may be acute polyarthritis with painful swelling of the joints, redness and increased temperature of the overlying skin. 3. Chronic recurrent polyarthritis with effusion is a third articular manifestation. There may be recurrent episodes of effusion into joints, but these do not result in deformity or permanent impairment of function. The wide variety of cutaneous lesions occurring in lymphogranuloma venereum are generalized or limited to the region especially affected by the virus. In the latter group belong the ulcerative disorders classified by Wien and Perlstein as (1) simple ulceration of the skin, (2) ulceration secondary to involvement of lymph nodes and (3) ulceration developing on an esthiomene. The generalized cutaneous lesions are either erythema nodosum or erythema multiforme. Hickam presents the histories of 4 patients with lymphogranuloma venereum. The articular manifestations in these patients resembled those described by other authors except for the additional presence of acute tenosynovitis and bursitis with effusion. All forms of involvement subsided rapidly. A generalized pustular eruption occurred in 3 patients. In 2 patients it was thought to be evoked by the intradermal Frei test with chick embryo antigen (lygranum). Two patients had severe reactions to the Frei test with an exacerbation of certain of the manifestations of the disease. It is suggested that the preparation of chick embryo antigen be diluted for use for patients whose disease appears to be in an active stage.

Cutaneous Diphtheria.—Diphtheritic infection of the skin has been noted with considerable frequency among the armed forces. It exists in two forms: a rare, acute variety almost invariably associated with faucial or nasal diphtheria, consisting of a solitary lesion which may develop on an intact or previously abraded site, and a chronic form characterized by multiple indolent lesions, which occasionally develop from the acute type but more commonly result from superinfection by Corynebacterium diphtheriae of preexisting dermatoses such as pyodermas, scabies and fungous infections. The treatment consists in the use of diphtheria antitoxin in fairly large doses. Saffron reports the case of a soldier aged 31 who had an acute faucial and cutaneous diphtheria. Thirty thousand units of diphtheria antitoxin was given intramuscularly on the first day and 28,000 units the following day. The axillary lesion was treated by local wet applications of 2,500 units of penicillin every three hours. The temperature had fallen to normal within twenty-four hours, and the throat cleared completely within seven days. Pain and swelling disappeared in the axillary region within forty-eight hours, but the lesion healed slowly. The membrane

disappeared after a few days, but the necrotic base persisted and eighteen days were required for complete healing. This is the first reported instance of local use of penicillin in cutaneous diphtheria.

Neoplastic Diseases of Human Hypophysis. J. E. Kraus.—p. 343.

Pathology of Anaphylaxis Due to Sulfonamide Drugs.—The universal use of sulfonamide compounds and the discovery that they can act as antigens capable of eliciting fatal reactions have for the first time made possible the study of a large number of relatively slow but fatal anaphylactic reactions. Black-Schaffer describes the lesions discovered in 5 cases of anaphylactic death following therapeutic use of sulfonamide compounds. The basic lesion, as in experimental protein anaphylaxis, is necrotizing fibrinoid arteritis of the smaller vessels. The cellular exudate is monocytic in composition. The reticuloendothelial system is hyperplastic; in the spleen, the lymph nodes and the marrow the sinusoids may be crowded with macrophages showing phagocytosis of erythrocytes and leukocytes. This phenomenon may be the morphologic expression of the addition of some substance to the blood cells (conjugated sulfonamide group?) that renders them "foreign." The possibility that these homologous "foreign cells" may elicit the production of antibodies is suggested and may account for the hemolytic anemia, the leukopenia and the agranulocytosis. The available evidence indicates that the nephrosis in cases of reaction to treatment with sulfonamide compounds is a form of anaphylactic renal reaction. The identity of the lesions with those produced in a few human subjects and many animals by known species-foreign proteins, the knowledge that the sulfonamide compounds may convert homologous proteins into allergens and the fact that characteristic clinical syndromes follow the administration of the drugs constitute sufficient evidence to justify the concept of the anaphylactic nature of the lesions described.

*Report of Case of Idiopathic Congenital (and Probably Familial) Methemoglobinemia. A. Graybiel, J. L. Lilienthal Jr. and R. L. Riley. —p. 155.
Report of Case of Acute Interstitial Fibrosis of Lungs. H. Eder, C. Van Zandt Hawn and G. Thorn.—p. 163.

Idiopathic Congenital Methemoglobinemia.—Graybiel and his associates report the history of a boy who had been blue at birth and had remained so. He was troubled with fatigue and shortness of breath. At the age of 17 he left school and began to do light work. His diet was adequate and contained relatively large amounts of ascorbic acid. He had never taken drugs known to cause cyanosis or pigmentation. The family history revealed that a cousin also had been blue at birth and had died at 14. Examination revealed that the youth, now 19, had intense cyanosis of the ears, tongue, lips and especially the gingival margins of the gums. The scleral vessels were dark blue, and the retinal arteries and veins appeared almost black. A sample of arterial blood was chocolate colored. Tests indicated that 38 per cent of the circulating blood pigment could not combine with carbon monoxide and presumably was methemoglobin. This presumption was confirmed by spectroscopic analysis. The patient was given 100 mg. of ascorbic acid and 0.6 Gm. of sodium bicarbonate three times daily by mouth. Four days later the patient's scleras appeared to be less injected and the lips slightly less cyanotic; the methemoglobin percentage, determined by the carbon monoxide method, had fallen. Later the daily dose of ascorbic acid and of sodium bicarbonate was doubled and after nineteen days of treatment the methemoglobin concentration had fallen from 8.1 Gm. to 1.7 Gm. and the normal hemoglobin had increased from 13.1 Gm. to 15.8 Gm. Exercise tolerance tests showed great improvement in the capacity for hard physical work. The striking clinical feature of this case of idiopathic congenital methemoglobinemia was the intense cyanosis, which was out of proportion to the other clinical aspects. Attention is drawn to the features which are common to both idiopathic methemoglobinemia and congenital heart disease with cyanosis. Simple inspection of a drop of the patient's blood may provide the differential clue. It is likely that some cyanotic patients now regarded as having congenital heart disease have, in fact, methemoglobinemia. Ascorbic acid, a biologic reducing substance, is capable of converting methemoglobin to normal hemoglobin in vivo.

Chemotherapy of Tuberculosis.—Pfuetze reviews experiences with several sulfonamides in the treatment of tuberculosis. Promin, though probably of value in some cases, is too toxic for widespread general use. Diasone, though less toxic than promin, clinically falls far short of original expectations. Promizole, which is much less toxic than either of the other two, is still under clinical investigation, thus precluding accurate evaluation at this time.

Penicillin by Mouth with Aluminum Dihydroxy Aminoacetate.—Paul and his associates say that recently the new aluminum buffer antacid aluminum dihydroxy aminoacetate (Alglyn) has been investigated at the University of Iowa Hospital. This is a combination of aluminum with aminoacetic acid containing 18.3 per cent aluminum and 9.3 per cent nitrogen. The aminoacetic acid causes rapid buffering action, while the aluminum gives a prolonged effect. The authors used oral

medication with penicillin and aluminum dihydroxy aminoacetate in the treatment of 16 patients with gonorrhea and 1 with sinusitis complicating scarlet fever. The patients with gonorrhea were given 100,000 to 300,000 units of penicillin, while a woman aged 24 showed clinical and bacteriologic cure with only 100,000 units of penicillin given as a single dose. Within two hours gonococci could no longer be cultured from the cervix. A youth aged 19, who developed acute sinusitis during the course of scarlet fever and could not tolerate sulfadiazine, made a prompt clinical recovery after 320,000 units of penicillin in divided doses was given. Alglyn, because of its immediate and prolonged buffering action, is a satisfactory antacid to combine with penicillin for oral administration.

Development of Bone Sarcoma Following Irradiation.—The literature contains reports of 24 patients who developed bone sarcoma following exposure to x-rays or radium. Seventeen of these tumors resulted from roentgen therapy for tuberculous arthritis. One followed similar treatment for acute arthritis. In 6 cases bone sarcoma followed exposure to radium. Hatcher reports histories of 3 patients in whom irradiation appears to have been responsible for the development of bone sarcoma. In each of these cases the tumor arose in normal bone which had been in the field of irradiation directed toward earlier independent tumors. Two are chondrosarcomas and 1 is a fibrosarcoma with tumor cartilage. In all cases except 1 the amount of irradiation was large and was administered in fractional doses over a long period. The interval between irradiation and recognition of irradiation-produced sarcoma is long. The median time in reported cases is six years.

Excision and Bone Grafting in Benign Giant Cell Tumors.—Meyerding reports 40 cases of benign giant cell tumor of bone in which excision of the tumor and bone grafting were employed. A history of injury was elicited in 23 cases. The average duration of symptoms before operation was 23.5 months. Treatment prior to consultation and operation at the clinic had consisted of immobilization, diathermy, elimination of foci of infection, arthritis vaccines, aspiration, irradiation, excision and irradiation, and excision and bone grafting. In 2 of the cases a diagnosis of sarcoma had been made and amputation had been advised. Diagnosis of benign giant cell tumor usually can be made on the basis of the history and the clinical and roentgenographic findings. Close cooperation between the pathologist and the surgeon at the time of the operation is essential. The differential diagnosis of benign giant cell tumor and malignant giant cell sarcoma cannot be made on the basis of roentgenographic interpretation alone. Adequate exposure and the removal of a block of tissue will make possible microscopic examination. Should there be doubt that the lesion is benign, the wound should be closed and the pathologist given additional time. This sometimes is necessary in cases in which a previous operation has been performed, in cases in which irradiation has been employed and in cases in which the tumor is infected; it is rarely necessary if previous treatment has not been given. Curettage of a giant cell tumor should consist of a complete excision. Usually the graft is taken from the tibia, fibula, ilium or a sound portion of the involved bone. The best results are obtained in cases in which the cavity is packed firmly with autogenous bone, and when complete rest is assured by a plaster of paris cast. In cases in which the tumor is situated in the region of the knee or the ankle, weight bearing should be avoided until the roentgenographic examination discloses sufficient deposition of bone to stand the stress and strain. Good functional results were obtained in 38 of the 40 cases. Excision of the tumor and bone grafting is a safe procedure in properly selected cases, and it tends to prevent deformity and disability.

Treatment of Poliomyelitis.—Johnson recommends in the acute stage bed rest, sedation for restlessness and pain and half-shell plaster molds or "Toronto" type splints for paralyzed, weakened or tender extremities in positions of relaxation. Frequent checks are made of muscle power. Hyperesthesia or muscle tenderness is also checked. Except in the encephalitic type, the author has not had clinical evidence of spasticity in the paralyzed extremities. Stiff necks and backs are usual in the early days, but they tend to disappear spontaneously. Radiant heat is administered intermittently as a stimulant to local circulation. In the convalescent period gentle massage is administered to the paralyzed or weakened groups and is increased slowly in depth and force as soon as hypersensitivity permits. Limited passive motion is begun in joints where muscle power is below 50 per cent, and active motion is started in an increasing range as the muscles grow in strength. Graduated exercises are given for weakened muscles. Patients who seem destined to have some disability are turned from invalidism and self pity toward an attitude of adaptability and compensation. In the wards the children help one another to achieve this end. Ward patients do much better in this respect than patients in private rooms. Later, underwater exercise in pools is used. The benefit of a crusade of the Sister Kenny type is that it makes us reexamine our own therapeutic procedures. Johnson has remained unimpressed by the claims of superiority of the Sister Kenny treatment. Patients are not cured, they recover; and the author rates recovery not in case units, because misleading statistics are produced in this way. The proper unit is the weakened and paralyzed muscle, and recovery is judged on final muscle power as compared with the original degree of paralysis. The record of each muscle is kept separately. For this analysis the author has selected ten commonly paralyzed and important muscles: gluteus maximus, gluteus medius, quadriceps, hamstrings, gastrocnemius, tibialis anterior, deltoid, biceps humeri, triceps brachi and opponens pollicis. Figures shown in tables concern 64 patients. The paralyzed muscle units reported are 350 in the lower extremity and 106 in the upper extremity. All muscles should have three months of careful and painstaking protection and treatment comparable to that given in peripheral nerve lesions. At the end of such a three months regimen a prognosis of recovery can be arrived at, for the muscles can then be differentiated into three categories: (*a*) Those which have not recovered to a point of 30 per cent of power in three months. No return of useful power is to be expected, and these make up the permanently paralyzed extremities. (*b*) Those which by this time have 80 per cent or more power and can be counted on to function satisfactorily without further treatment except general supervision. (*c*) The group which has demonstrated some return of

power and has a three month level of 30 to 75 per cent. These have potentiality for further recovery to a point where useful function can be restored. These cases are the important ones as far as further active treatment is concerned. No appreciable recovery continues beyond eighteen months even under ideal conditions, but untreated or inadequately treated cases have been salvaged by this regimen as late as six to ten years after the acute attack, indicating a previous nerve recovery which had been masked or nullified by the overstretching or overfatigue of the muscle or by opposing contracture.

Margarine in Diet of Rats.—Deuel and his associates report observations on reproduction and growth rate in ten generations of rats fed with a modification of the Sherman diet B in which butterfat has been replaced by margarine fat fortified with vitamin A. The growth rate considerably exceeded that obtained with animals on the stock diet and progressively improved with the later generations. A vegetable fat such as that contained in a margarine can serve adequately in place of butterfat for growth and reproduction on a diet otherwise nutritionally satisfactory.

Composition of Typical Mexican Foods.—Cravioto B. and his associates analyzed 112 samples of food from Mexico for the content of carotene, thiamine, riboflavin, niacin, ascorbic acid, calcium, phosphorus, iron, nitrogen, ash and total solids. Many of these foods were analyzed for the first time. The kinds and nutritional qualities of the foods of Mexico are so different from those of the United States that the nutrition program in Mexico should be based on the nutrient content of Mexican foods. Many Mexican foods are richer in specific nutrients than foods in the United States. It is probable that the Mexican diet is more adequate in ascorbic acid, thiamine, phosphorus and calcium than in riboflavin, niacin and quality protein.

Effect of Atabrine on Thiamine Deficiency.—According to Hegsted and his associates previous studies on the relation of nutrition to the tolerance of atabrine by rats led to the demonstration of a "choline-like" or "choline sparing" action of atabrine. Addition of atabrine to a thiamine deficient diet for rats delayed loss of weight, onset of symptoms and death. Low levels of thiamine produced greater gains in animals receiving atabrine than in controls. Atabrine thus has a "thiamine sparing" action.

Pain in Paroxysmal Tachycardia.—Wolff analyzes the clinical data of 253 cases of paroxysmal tachycardia with reference to the occurrence of chest pain. It occurred in 16 per cent of the cases in this series. Anginal pain is invariably provoked by paroxysms of rapid heart action in patients with angina pectoris, provided the ventricular rate is 150 (the critical level) or more. In the great majority of cases in which paroxysmal tachycardia induces anginal pain, coronary heart disease, usually with angina pectoris, is present. The association of anginal pain and paroxysmal tachycardia with ventricular rates under 150 or regardless of the rate in patients without a history of angina pectoris suggests various diagnostic possibilities,

both cardiac and noncardiac. Paroxysmal tachycardia does not always enhance the pain of acute myocardial infarction. The failure of paroxysmal tachycardia to induce pain does not exclude the presence of coronary heart disease, acute, recent or old myocardial infarction or angina pectoris in the past.

Mucosal Atrophy and Carcinoma of Stomach.—In the laboratory of Surgical Pathology, Columbia University, a number of surgically resected stomachs were treated by opening along the greater curvature, pinning out on a cork board, fixing in Bouin's fluid, and taking ten or more sections from different areas according to a definite plan. There were thus made available multiple sections from 150 stomachs, 50 with gastric carcinoma, 50 with gastric ulcer and 50 without gastric ulcer or carcinoma which were removed because of duodenal ulcer. The study revealed that mucosal atrophy may appear as early as the third decade and is found with increasing frequency and extent in the succeeding decades of life. In comparable groups of stomachs mucosal atrophy is found in a larger number and tends to be more widespread in those with cancer than in those without cancer. But when one tries to find actual progression from altered mucosal glands, gastric or intestinal in type, cystic or not, distorted or regular, it is realized that it is impossible to tell when there is juxtaposition of carcinoma and mucosal gland, whether the carcinoma is invading the gland or developing from its epithelial cells. In occasional stomachs with carcinomas multiple sections from various areas failed to show epithelial changes in some, while others showed only minimal changes. While atrophy of the gastric mucosal epithelium and cyst formation were present to a greater degree and in larger numbers in stomachs with carcinomas than in comparable stomachs without cancer, the exact relationship between these two conditions remained undetermined.

Surgical Treatment of Chronic Constrictive Pericarditis.—*In a series of* 18 cases reported by Heuer and Stewart enlargement of the liver was present in all, ascites in 15, edema of the extremities in 11 and pleural effusion in 8. Dyspnea on exertion or at rest was present in 17 and cyanosis in 14. Distention of the peripheral veins and an increase in venous pressure were present in all patients. The diagnosis of chronic constrictive pericarditis should be considered in patients with signs of congestive heart failure, in the absence of the common causes of this condition. The disease is commonly confused with mitral stenosis, cirrhosis of the liver, polyserositis and nutritional or other edemas. Tricuspid disease and mediastinal tumors may occasionally be wrongly diagnosed. All of the 18 patients were subjected to the operation of pericardiectomy. The authors stress the importance of preoperative treatment and careful attention to details in the operative procedure. They have performed 19 operations on 18 patients without a postoperative mortality. Seven patients are classified as cured over periods varying from one and a half to eight and a half years. Three patients more recently operated on have shown such improvement as to warrant the expectation of a cure. Four patients are greatly improved over periods of from three to six and one-half years. One patient is moderately improved and is living six years after operations. Four patients were not improved by the operation. Of these 1 is living seven years after operation and 3 have died.

Tests for Epidemic Typhus Vaccines.—According to Donovick and Wyckoff the most direct laboratory method of testing epidemic typhus vaccine is one in which the immunity of vaccinated guinea pigs is challenged by injecting enough infectious tissue to produce typical guinea pig typhus in control animals. This test is hard to use routinely because it requires several weeks to carry out. Bengtson and Topping's development of the complement fixation test for typhus gives one of several other feasible ways for evaluating typhus vaccine. The authors compared the complement fixing antibody titers and results of protection tests on guinea pigs injected with many different typhus vaccines. Results of these two tests run parallel in the sense that vaccines which show an especially high degree of protective power also induce a particularly high average complement fixing antibody titer. Present typhus vaccines are superior to those prepared a year ago.

Patent Ductus Arteriosus.—Of 28 consecutive patients with patent ductus arteriosus, operation on 14 was judged unnecessary or undesirable. Two died, 1 from intercurrent infection and 1 from subacute bacterial endarteritis. Slight deterioration in physical capacity was observed in 3. Two women married and have borne families without undue distress. In 1 patient, a boy of 6, the ductus closed spontaneously. Distinct improvement in the general health and physical capacity was observed in 6 of the 14 patients submitted to surgery. Four obtained less benefit than anticipated, chiefly because complete obliteration of the ductus was not always obtained. Two patients died after operation. Gilchrist puts emphasis on the value of repeated x-ray examinations in the diagnosis of the condition. Two patients operated on because of bacterial endarteritis died. Death in each instance was attributed to massive pulmonary collapse. The selection of patients for surgery demands careful consideration. The main factors to bear in mind are the age of the patient and the degree of cardiac embarrassment. In general, the younger patient should be accepted for surgery when symptoms are minimal, in the hope that by ductal occlusion the child may grow and develop normally. In older patients, on account of the increasing operative hazards, surgery can be justified only when symptoms, being more severe, warrant the risk. In the presence of an infected ductus, ligation should be undertaken without delay at any age.

Clinical Effects of Use of Pneumatic Tools.—Hunter and his associates review observation on 286 workers who used pneumatic tools. White fingers were found in 48 riveters, 27 caulkers and 77 fettlers. The syndrome usually developed after they had been on the work for from two to five years. It occurred most frequently among workers who were using tools with a vibration rate of 2,000 to 3,000 a minute. The condition occurred most often in cold weather, and cold is probably a precipitating factor. White fingers rarely caused gross disability, but in 3 cases the condition was severe enough to make the men change their occupation. Arthritic changes were rare and there was no convincing evidence that they can be brought about solely by the use of pneumatic tools. The possibility, however, cannot be completely dismissed. Small areas of decalcification or bone cysts in the carpal bones were found in 35 riveters, 14 caulkers, 51 fettlers and 19 holders-up. This condition may be caused by repeated trauma, but it is not confined to workers who use pneumatic tools. The cysts cause no disability, and there is no evidence that they predispose to arthritis or fracture. Ulnar paresis was found in 3 cases, but only 1 case of Dupuytren's contracture was found in 286 workers. Bruising on the dorsum of the hand occurs in riveters when driving rivets in a vertical direction.

Congenital Deficiency of Pericardium with Bronchogenic Cyst.—A girl aged 19 had partial deficiency of the pericardium associated with a solitary bronchogenic cyst, both on the left side. Rusby and Sellors review the literature relating to pericardial deficiency and show that theirs is the eightieth case placed on record, the third to be recognized during life and the only one carefully studied at operation. The symptoms of which the patient complained can be attributed to the lung cyst, which was removed. An uneventful recovery followed, and good health has been enjoyed since operation. The authors contend that the association of a lung cyst with a partial left-sided deficiency of pericardium lends weight to the view that the latter defect is the result of abnormal development with premature atrophy of the left duct of Cuvier. The name given to this condition by Keith, patency of the iter venosum, is believed to be accurate, and it possesses the added advantage of according well with the nomenclature in current use for other developmental abnormalities of the cardiovascular system.

Control of Hospital Infection of Wounds.—Williams and his associates undertook a survey in order to extend the observations of the effects of a revised dressing technic on the incidence of added hospital infection. As in previous investigations, the survey was made in terms of Streptococcus pyogenes, but these observations differ from them in that the authors examined wounds and personnel for the presence of Staphylococcus aureus as well and tried to assess the magnitude of the reservoirs of both these infecting organisms in the environment. During a control observation period of ten weeks the added infection rate per wound-week at risk in a surgical ward dealing mainly with septic wounds of the hands was

13.9 per cent for Streptococcus pyogenes and 100 per cent for Staphylococcus aureus. During a test period of twenty-six weeks, after the adoption of a revised wound dressing technic, the added infection rates were 0.75 per cent for Streptococcus pyogenes and 17.8 per cent for Staphylococcus aureus. The carrier and infection rates for the two organisms in the noses, throats and wounds of the patients and in the noses and throats of the nursing staff were similar in both periods. The number of wound weeks at risk was higher in the test than in the control period. The reduction in added infection may therefore be attributed to the revision of the dressing technic.

*Anatomicopathologic Verification of Atelectasis in Epituberculosis in Children. G. Llodra and A. Guzmán.—p. 97.
Mediastinal Syndrome and Leukemia. J. Meneghello, H. Niemeyer and R. Eberhard.—p. 153.

Atelectasis in Epituberculosis of Children.—Llodra and Guzmán performed necropsies on 17 children with a clinical history of epituberculosis who died from accidents, from nontuberculous disease or from extrapulmonary tuberculosis. Pulmonary atelectasis was found to be the pathologic basis of epituberculosis in all cases. Atelectasis was recent in some cases and chronic in others. It was caused in some by constriction of the bronchi the result of compression by enlarged regional lymph nodes and in others by partial obstruction of the bronchi by local accumulation of tuberculous exudate. Old atelectasis manifested by foci of pulmonary induration was frequently associated with bronchiectasis.

*Treatment of Scarlet Fever with Convalescent Blood.—P. Klein.—p. 422.

Atabrine and Nervous System.—Experiments on rabbits and cats revealed certain secondary effects on the central nervous system of these animals. Psychosis and motor excitement were caused by suicidal attempts with large doses of atabrine (1.9 to 9 Gm.). Vollmer and Liebig report 4 recurrent cases of tertian malaria in which secondary effects on the central nervous system were observed. The occurrence of these reactions was in contrast to the opinion of other authors, who believed that reactions of this type do not result from the administration of therapeutic doses of the drug. The incidence (4 in 450 cases) was low. Psychosis resulted in 3 cases from intramuscular injection of atabrine, and psychosis associated with bulbar paralysis and flaccid paralysis of the lower extremities in 1 case. The aforementioned disturbances were of short duration. There were no irreversible cases.

Convalescent Blood Treatment of Scarlet Fever.—Klein obtained gratifying results from transfusion of convalescent blood in 34 severe toxic cases selected from 450 cases of scarlet fever. Mild and medium severe cases do not require this type of treatment. One transfusion was given to 28 patients, 2 transfusions to 5 and 4 transfusions to 1 patient. The amount of blood transfused varied from 110 to 300 cc., the usual amount being 220 cc. to 280 cc. In the majority of the cases the transfusion was given in the acute stage of the disease after the fourth day but not later than the tenth day. Good results were obtained likewise in 2 cases in which the transfusion was performed on the thirty-fifth day of the disease. The donors were convalescent after the third week of the disease. A pronounced improvement in the general condition is followed by a drop in temperature and decrease in pulse rate. The rash loses its color and desquamation sets in earlier, but these results are of minor importance. Complications occur in spite of the treatment. There is no danger of serum sickness, and the transfusion may be repeated as often as necessary. One cc. of racemic ephedrine administered at the start of the transfusion proved effective in preventing shock. A blood bank for stored convalescent blood is suggested. Good results obtained from transfusion of normal blood in 7 cases of scarlet fever suggest that normal blood may be used instead of convalescent blood when the latter cannot be obtained.

*Importance of Lymphatic Tissues (Thymus, Spleen, Lymph Nodes) in Pathogenesis of Tetany in Infants. A. Nitschke.—p. 16.

Lymphatic Tissue and Tetany of Infants.—Nitschke produced in rabbits the characteristic syndrome of tetany by injecting the precipitates of urine of 9 infants with tetany. The syndrome was manifested by adynamia, lowering of the blood calcium level, electric hyperexcitability and cramps. Recovery of the infants from clinical spasmophilia followed administration of irradiated ergosterol, but prolonged excretion of tetany producing substance in the urine continued for three to four weeks thereafter. Injection of urinary precipitates of 5 normal infants into rabbits did not produce lowering of the blood calcium level in the animals. The effects on the rabbits of the injection of urinary precipitates from infants with tetany resembled in its clinical aspect and the time of appearance of the symptoms and their duration the effects of administering extracts of thymus, spleen and lymph nodes previously reported by the author. This suggests that the two effects were caused by the same chemical substance. The new observations seem to prove the concept previously advanced that the lymphatic system is to be considered as an endocrine unity which produces, when hyperfunctioning, the clinical picture of tetany by its antagonistic effect on the parathyroids.

Surgical Treatment of Pylorospasm. A. Bardy.—p. 71.
*Significance of Blood Group Characteristics in Serum and Plasma Transfusions. K. Halvorsen.—p. 80.

Citric Acid in Serum in Hepatic and Biliary Diseases.—Sjöströms demonstrated in 1937 that the determination of the citric acid content in the blood serum is of aid in the diagnosis of diseases of the liver and the bile passages. The enzymatic chemical method of Thunberg is used for the determination of the citric acid. Hagelstam describes experiences with the Thunberg method. On the basis of studies on healthy persons he considers 24.35 micrograms per cubic centimeter the normal mean and 28 micrograms the normal maximum. Studies on patients with hepatitis revealed increased values in all severe cases. In the cases in which galactose epinephrine or Takata tests were conducted concurrently with the citric acid test the latter was found to be twice as sensitive as the galactose and Takata tests, while the epinephrine test showed the same sensitivity as the citric acid test. In patients with

stenosis of the common bile duct all but 1 showed normal values. Many patients with diseases of the gallbladder exhibited increased citric acid values. The author concludes that the citric acid test is of great value in differentiating between hepatitis and obstructive jaundice.

Blood Group Characteristics in Serum and Plasma Transfusions.—Halvorsen stresses that, in producing serum and plasma for therapeutic use, consideration must be taken of the blood group characteristics, and an attempt should be made to prepare a serum which is as free of these as possible. By mixing in suitable proportions, it is possible to prepare serums which are practically free of both anti-A and anti-B agglutinins as well as of antigens (agglutinogens) A and B. If citrated blood is used, the proportions 2 O, 1 A, 1 B will give a mixed plasma which is free of isoagglutinins and contains little antigen A and B regardless of the agglutinin titer of the individual components. If only serum or plasma is mixed, a mixture of equal parts of A and B serum or plasma with an isoagglutinin titer of 64 to 128 will be practically free of both isoagglutinins and antigen A and B. About half of the A donors and one third of the B donors can be expected to lie within this titer range.

Cervical Disk Prolapse.—In 5 of 285 patients with vertebral disk prolapse, the involved disk was in the cervical region: in 3 cases it was the sixth cervical intravertebral disk, in 1 case the fifth and in 1 case the fourth intravertebral disk. Four of the patients were men between the ages of 33 and 50, and 1 was a woman aged 46. The history revealed traumatic injury to the spinal cord in 3 of the 5 cases. Pain was the most common initial symptom. Only 1 of the patients had quadriplegia; 2 patients presented unilateral radicular paresis and atrophy, 1 of them with inferior paraparesis; 1 patient had inferior paraparesis only, and 1 had normal neurologic findings. The Brown-Séquard syndrome was present in 1 case. Sphincter disturbances were present in 1 case. X-ray examination revealed narrowing of the involved intravertebral space in 3; in all 5 a typical spondylosis deformans with osteophytes was demonstrated in the cervical spine, most pronounced at the level of the ruptured disk. Iodized oil myelography showed nothing characteristic of disk prolapse. A partial block was found in 2 cases and a total block was seen in 2. The three distinct syndromes described by Stookey as typical of cervical disk prolapse may be useful if the differential diagnosis is difficult between a small cervical disk prolapse and a case of intrinsic disease of the cord. But if the disk prolapse is large the syndromes of Stookey will not be of any help in the differential diagnosis between intraspinal tumor and disk prolapse. The history of a specific traumatic injury to the cervical spine combined with signs of an intraspinal tumor in this region should be suggestive of a cervical disk prolapse. These symptoms, combined with x-ray signs of localized spondylosis deformans of the cervical spine, and especially narrowing of an intravertebral space, would also point to disk prolapse.

Electrocoagulation of Gasserian Ganglion.—In the neurosurgical department of Rigshospitalet in Copenhagen 85 patients with trigeminal neuralgia have been treated during the last six years with electrocoagulation of the gasserian ganglion by the Kirschner method. The location of the foramen ovale having been found percutaneously with an apparatus specially designed by Kirschner, the ganglion is punctured with a trocar; the stylet is removed and a cautery probe is introduced with which the ganglion is electrocoagulated. The operation takes a few minutes. The patients were between the ages of 19 and 92. There were 54 women and 32 men. The duration of the neuralgia was on an average six years, the longest thirty years and the shortest three months. The right side was affected in 55 cases, the left in 28 cases; 3 cases were bilateral, 74 patients had major and 12 had atypical trigeminal neuralgia. Primary relief of symptoms was obtained in 66 cases, the remaining 20 having to undergo other treatment. The longest follow-up was fifty-one months, the shortest three months. The follow-up revealed that 25 patients were relieved of pain and 7 were substantially improved; 13 patients had a recurrence, which in most cases yielded to a repeated electrocoagulation. There were no fatal cases. The best results, both as to primary relief of symptoms and as to prevention of recurrence, were obtained in trigeminal neuralgia of the third division. Oddsson suggests that most patients with major trigeminal neuralgia should be treated with temporal retrogasserian neurotomy. If the patient is not likely to stand the operation, alcoholic injection or neurexeresis may be carried out in neuralgia of the first and second divisions, while in neuralgia of the third and perhaps also of the second division electrocoagulation of Kirschner should be performed. In special cases section of the sensory root alongside the pons by Dandy's subcerebellar route may be considered, but it seems likely that this operation will be superseded by the tractotomy of Sjöqvist, which has definite advantages.

*Neurologic Symptoms in Arthritis Deformans Humeroscapularis. K. Mårtensson.—p. 271.

Bone Changes in Diseases of Blood.—Characteristic bone changes in Cooley's erythroblastic anemia, sickle cell anemia and hereditary jaundice are seen almost exclusively in children and most often and in a most accentuated form in the cranium. In acute leukosis, where the bone symptoms are more important than in chronic leukosis, they may cause pain in the joints suggestive of rheumatic fever. In other forms of acute leukosis Baty and Vogt's symptom often occurs at an early stage and the x-ray appearance may establish the diagnosis before the typical blood picture appears. Relatively grave changes which simulate spondylitis may be seen in both children and adults. The bone marrow in aleukemic myeloid splenomegaly may be hyperplastic, apparently normal or fibrotic. Myelosclerosis is most often accompanied by osteosclerosis. The process need not affect the entire bony system. In lymphogranulomatosis maligna the hematogenic type of bone changes can be diagnosed by bone biopsy. In the local forms with involvement of the bone marrow the processes are usually destructive, but they may be sclerotic. In lymphogranulomatosis benigna there are cystoid clarifications in the small bones of the hands and feet; the joints are as a rule intact. In Gaucher's disease the specific tissue is always found in the bone marrow. In the long bones it may by its growth distend the bone. In Hand-Schuller-Christian's disease multiple bone defects constitute a cardinal symptom. Karscher's is the only general work on bone changes in disease of the blood; however, he considers them only from the radiologic point of view.

Neurologic Symptoms in Humeroscapular Arthrosis Deformans.—Mårtensson finds that in this disease pain and muscle hyperalgesia are due to irritation of the sensory end apparatus of the joints; transmission of pain takes place in the region of the fifth or sixth cervical segment or eventually both. Section of the affected sensory root may in suitable cases overcome the pain and lessen, perhaps even overcome, the limitation of movement.

Book Notices

Bronchial Asthma. By Leon Unger, B.S., M.D., F.A.C.P., Assistant Professor, Department of Medicine, Northwestern University Medical School, Chicago. Introduction by Morris Fishbein, M.D., Editor, Journal of the American Medical Association, Chicago. Cloth. Price, $9. Pp. 724, with illustrations. Springfield, Ill., & Baltimore: Charles C Thomas, 1945.

This is a comprehensive treatise on the subject of bronchial asthma. It includes an excellent discussion of the clinical phases of asthma and goes into a minute consideration of the allergic factors involved in its production. The clinical section of the book takes up the history, terminology, etiology, pathology, symptomatology, direct and differential diagnosis and treatment of bronchial asthma. These chapters are thorough and complete and include an excellent bibliography. The chapter on treatment should be of great practical value to the clinician, including as it does all known forms of therapy for this condition. Much that appears in the book should interest the physician who has already devoted some time and effort to the study of allergy. The laboratory section contains much useful information such as methods of preparation of extracts and the technic of pollen counts. The third part of the book is a compilation of detailed information on the sources of various allergens, elimination diets, instructions to patients and "patent medicines" used in asthma. The book is written in an easy, flowing style. It is well documented. The publishers did an excellent job with the format and the printing. The illustrations are instructive and helpful. The book should be of value to the internist as well as the allergist. It is a good clinical treatise on the subject of bronchial asthma and will make a valuable addition to one's medical library.

Primate Malaria. By S. D. Aberle, M.D. Issued by the Office of Medical Information (under grant of the Johnson & Johnson Research Foundation) March 1945. National Research Council, Division of Medical Sciences. Paper. Pp. 171, with 12 plates. Washington, D. C., 1945.

This monograph, which was issued by the Office of Medical Information of the National Research Council, is designed to give research workers a concise review and ready reference to the work published on the malaria of primates, exclusive of man. It has been prepared in association with the chairman, Dr. Robert S. Loeb, and the secretary, Dr. George A. Carden Jr., of the Board for the Coordination of Malarial Studies. Each section has been compiled with the aid of one or more of the American workers in the field of primate malaria.

There are nine main sections. The first section, on parasites, hosts, vectors and transmission of parasites, is largely contained in five extensive tables, which include such subjects as the prevalence of natural malarial infections, lists of species of primate malarial parasites with their natural and experimental hosts, classifications of hosts and parasites and transmissibility of the parasites. The second section consists of a brief account of the metabolism of Plasmodium knowlesi. The third section gives a summary of the course of various infections, with special reference to the stages of the infection, development of the parasitemia, hematology and body temperature. The fourth section, on the chemotherapy of primate malaria, consists chiefly of two extensive tables, the first of which (table 7) is a summary of the preparations used in treating primate malaria with the results of the treatments and the second of which (table 8) gives a review of each paper from which the previous summary table is constructed and includes the dosage of drug, method of treatment and antimalarial activity. The fifth section, on immunity, is a review of both the humoral and the cellular aspects. The seventh section deals with both microscopic and gross pathology. The eighth section, on morphology, consists of plates, including a reproduction in color of Gonder and von Berenberg-Gossler's description of Plasmodium kochi, a series of black and white plates showing the morphology and asexual cycles of Plasmodium cynomolgi, Plasmodium inui, Plasmodium knowlesi and Plasmodium brasilianum, a plate from Taliaferro and Cannon showing the phagocytic reactions during immunity to P. brasilianum and four plates from Taliaferro and Mulligan illustrating the histopathology of infections with P. knowlesi and P. cynomolgi. The eighth section is a description, classification and a key for identifying the macaques, written by Remington Kellogg. The final section is a bibliography consisting of 456 references. It is complete through Oct. 1, 1944 and indicates, besides the original publication, reprints and reviews which occur in the *Tropical Diseases Bulletin* and *Biological Abstracts*.

This monograph is one of the most important research tools that has appeared in the field. It is not written for general reading but has most of the material, either condensed to a minimum of writing or put in the form of tables. The various collaborators give the work undoubted authority. The bibliography is unquestionably the most extensive yet compiled for the subject. In addition, the author has had access to and referred to much of the unpublished work supported by the Committee on Medical Research of the Office of Scientific Research and Development. Reproduction of the monograph itself is noteworthy. The text has been printed directly from typewritten material by a planograph method. Both the text and the illustrations are excellent.

Discovery of the Elements. By Mary Elvira Weeks. Fifth edition. Cloth. Price, $4. Pp. 578, with illustrations. Easton, Pa.: Journal of Chemical Education, 1945.

Regardless of specialty, every one active in scientific fields is interested in various phases of history. The discovery of the elements provides no exception, and physicians, chemists and others should enjoy many sections in this book. It is the sort of thing which is useful in any library but will have added value in the libraries of teachers, research workers and the like. Included are twenty-seven chapters of discussions ranging from elements known to the ancient world to individual elements such as chromium, tungsten, tellurium and selenium, the inert gases, radioactive elements and more recently discovered elements. The index is adequate. There is a good appendix on chronology, a list of the chemical elements with their atomic number, symbol and 1943 atomic weight and an excellent list of illustrations. In fact, there are 349 illustrations. Many people regard the elements as comparatively recent discoveries, and yet some of the substances now recognized as chemical elements have been known and used since earliest history. This book brings that history up to date by adequate illustration and frequent quotation. It is revealing to pore over these quotations when one considers the periods in which they were offered.

Electroencephalograms of Normal Children. By Charles E. Henry, Brush Foundation and Department of Anatomy, Western Reserve University School of Medicine, Cleveland. Monographs of the Society for Research in Child Development, Volume IX, No. 3 (Serial No. 39). Paper. Pp. 71, with 13 illustrations. Washington, D. C.: Society for Research in Child Development, National Research Council, 1944.

Successive electroencephalographic records were made of 95 presumably normal children over a period of from five to eight years. A single record was made also of 540 "normal" children between the ages of 4 and 19. In the majority of cases rates stabilize by the eighth year, with a frequency between nine and eleven per second. Females tend to have faster alpha frequencies than males and a larger proportion of low voltage fast records. Correlation between frequence and intelligence could not be demonstrated. In a group of 583 "normal" children 5 per cent had abnormal and 6.9 per cent questionably abnormal records, although some of these were found to be normal a year later. This is a complete detailed study made under the auspices of the Brush Foundation, a valuable reference and example for persons interested in electroencephalography or in the development of children.

The Relation Between Illumination and Visual Efficiency—the Effect of Brightness Contrast. By H. C. Weston. Medical Research Council, Industrial Health Research Board, Report No 87. Paper. Price, 9d Pp. 35, with illustrations. London: His Majesty's Stationery Office, 1945.

This is a report of the Industrial Health Research Board of the British Medical Research Council dealing with the effect of characteristics such as size, contrast and brightness on the facility with which objects can be seen. It is highly technical and presents most interesting experimental work and conclusions that are of interest mainly to psychologists, physicists and physiologists. Clinical applications are not included in this brochure.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM

To the Editor:—With the advent of newer forms of chemotherapy the time is proper for reassessing the merits of the Credé treatment in the prophylaxis of ophthalmia neonatorum. Several weeks ago I saw a newborn infant which, although it had received at birth an instillation of a 1 per cent solution of silver nitrate, developed gonorrheal ophthalmia. The infant was given sulfadiazine therapy by mouth, 1 grain per pound of body weight, and within four days was clinically and bacteriologically free from the disease. Since silver nitrate prophylaxis occasionally fails to prevent gonorrheal ophthalmia, and since it often produces a pronounced chemical conjunctivitis, would not a 1 per cent solution of sodium sulfadiazine or a solution of penicillin 200 Oxford units per cubic centimeter be of more value in prophylactic therapy? The latter chemotherapeutic agents are certainly less irritating than the silver nitrate solution.

Henry Rascoff, M.D., Brooklyn.

To the Editor:—Recently I have had 2 cases of gonorrheal ophthalmia in which 1 per cent silver nitrate solution in wax ampules was used. In using this solution should it be washed out immediately with isotonic solution of sodium chloride or should it be left in for a period of time? Should this procedure be left to the nurse in charge or should it always be done by the doctor? Is there any other solution more effective?

B. L. Lingeman, M.D., Crawfordsville, Ind.

ANSWER.—1. The Credé method of prophylaxis has been time tested since it was first advocated in 1880 and has proved to be remarkably effective in reducing the incidence of gonorrheal ophthalmia. It is still the standard procedure required by law in most states and should not be abandoned until certain proof of superior performance by a substitute method has been established. Its occasional failure can be attributed in most cases to faulty application or, in a few instances, to exceptionally prolonged labor which allows actual bacterial invasion of the conjunctiva to take place prior to birth. The chemical conjunctivitis produced by single-drop instillation of a 1 per cent solution of silver nitrate is of minor importance and should not militate against this use of the drug.

Single instillations of a 1 per cent solution of sodium sulfadiazine or a solution of penicillin (200 Oxford units per cubic centimeter) could not be expected to prove effective, as both agents require prolonged action to effect sterilization. In ointment form, however, effective concentrations can be maintained for from four to six hours, so that single instillations of 5 per cent sulfadiazine or 5 per cent sulfathiazole ointments, or of sodium penicillin ointment (500-1,000 Oxford units per cubic centimeter) or, preferably, three or four instillations of these preparations at four to six hour intervals, would be effective theoretically. The low tear production in infants during the first few weeks of life reduces the factor of dilution, which notably interferes with the local action of sulfonamide or penicillin in the adult eye. Oral administration of a total of 20 grains (1.3 Gm.) of sulfathiazole over a three day period, as recommended by Gleich, Blumberg and Mason (*Am. J. Dis. Child.* **67**:472 [June] 1944) would certainly be effective but would seem to introduce unnecessarily the risk of sulfonamide toxicity. The occasional occurrence of sulfonamide and penicillin resistant strains of gonococci would be a further complicating factor.

The sulfonamides would have the advantage of providing prophylaxis also against inclusion blennorrhea, which is the most important type of nongonococcic ophthalmia neonatorum and is not prevented by the Credé method. Penicillin is known to be inactive against this disease. The possibility of sensitizing the infants to the sulfonamides or to penicillin should receive consideration but would probably occur so exceptionally as to be insignificant. Final conclusions must await publication of the several research projects known to be in progress.

2. When 1 per cent silver nitrate is used, neutralization is unnecessary. Credé originally employed 2 per cent silver nitrate, and if this strength is used neutralization with isotonic solution of sodium chloride after an interval of a few seconds is advised. The instillation of silver nitrate should invariably be done by the physician, or at least supervised by him, to make certain that the drop reaches and spreads over the entire conjunctival and corneal surface. There is as yet no other solution known to be more effective as a prophylaxis against gonorrheal ophthalmia.

CONTROL OF TICKS IN TROPICAL MEXICO

To the Editor:—A patient and a group of friends have purchased land in Chiapas, Mexico. One difficulty at the camp which causes trouble every year is described by the patient as follows: "We are on the edge of the cattle country, and the grass and brush are full of ticks, some almost too small to be seen and others like small spiders. There are both hard and soft ticks. Almost every time we go out of the camp we return with our skin peppered with them. We detick at every opportunity, but still we get hundreds of bites. They spoiled our dispositions for the first month or two. Some of us are now developing a sort of immunity, but others are having real trouble. One girl has big festering sores, almost boils, all over her legs. Her whole legs swell and pain her; she has had some fever from them and has been really laid up for about three weeks. Usually we have small vesicles form and harden so that they itch like chickenpox. The glands in the groins swell and become tender." What can be suggested for this group?

Louis L. Sherman, M.D., Oakland, Calif.

ANSWER.—Serious annoyance from ticks is encountered in many parts of the tropics. The species which causes most of the annoyance in tropical Mexico is probably the Cayenne tick known scientifically as Amblyomma cajennense. The small specimens mentioned are seed ticks, the ones "like small spiders" are nymphs, and the larger ones are the adults, males and females. The latter engorge with blood of various wild and domestic animals, becoming as large as the end of the little finger, and then drop off and deposit five or six thousand eggs on the ground and die. The eggs soon hatch into seed ticks.

There is no very satisfactory way of eliminating these pests from an area that is frequented by livestock or wild animals that serve as hosts. Excluding such animals and keeping the grass and underbrush closely cut will ultimately materially reduce the numbers of the pests. Some control can also be effected by spraying around habitations and along paths and roadways with a solution containing 4 teaspoons of a 40 per cent solution of nicotine sulfate, ½0 ounce of soap and 2 ounces of sodium fluoride to 1 gallon of water. This spray will cause some burning of foliage. Much protection of the individual can be obtained by dressing to exclude the ticks. This involves wearing trousers inside high top shoes and having tightly closed flies on trousers and shirts. A rag soaked in kerosene and tied about the top of the shoes helps keep them off. Certain repellents have value in protecting individuals, but these are not at present available to civilians since the supplies are being devoted entirely to military uses.

MORPHINE AS A CAUSE OF DEATH

To the Editor:—Is there any record of hypersensitivity to morphine administered hypodermically in ¼ grain dosage? Is there record of such a dose's causing death by respiratory paralysis in adults? What is the smallest dose of morphine, administered hypodermically, known to cause death?

M.D., North Carolina.

ANSWER.—There is a considerable variation in the sensitiveness with which individuals react to morphine. Some individuals require much smaller doses of morphine to produce a given result than do others. This could be considered as a hypersensitivity to a usual dose. Elderly persons tolerate morphine poorly. A quarter of a grain of morphine is the usual dose used for an adult, although the official dose is smaller.

Reports of death by respiratory paralysis in adults caused by ¼ grain of morphine have not been found. However, if the respiration was much embarrassed from other causes, the morphine could conceivably aggravate the condition.

The average fatal dose of morphine in man is stated to be about 0.005 Gm. per kilogram of weight. There does not appear to be any record of the smallest dose of morphine administered hypodermically which is known to cause death.

SENSITIVITY TO SULFATHIAZOLE

To the Editor:—Is it reasonable to assign an acute flare-up of dormant phlebitis of the leg as a toxic reaction to the local use of sulfathiazole ointment? If there is a causal relationship, would it be a toxic manifestation or an allergic reaction? A patient sustained second degree burns of two fingers, and sulfathiazole ointment was applied. He subsequently developed a skin reaction of the extremities and also an acute exacerbation of a previously existing phlebitis in the leg. My review of the literature does not indicate phlebitis as an encountered complication following the use of the sulfonamides.

M.D., New York.

ANSWER.—It is to be assumed that the "skin reaction" of the extremities was a manifestation of hypersensitivity to sulfathiazole. It is difficult to interpret the genesis of the exacerbation of the phlebitis. While vascular lesions have occurred as a result of sensitivity to the sulfonamides, such as periarteritis nodosa, the appearance of thrombophlebitis has not been recorded. Therefore one cannot state that the phlebitis described in this case was a manifestation of sulfonamide sensitivity or toxicity.

PSEUDOBULBAR PALSY

To the Editor:—A white woman, aged 57, widowed, presents extreme dysarthria, mildly ataxic gait, emotional instability and moderate mental deterioration. These symptoms have been developing during the past two or three years, becoming progressively worse. Her father died at 74 from pneumonia; her mother is living at the age of 100; a brother died in a state hospital at the age of 62; the diagnosis was chronic bulbar paralysis with psychosis. He had had a neurologic condition for four or five years before his death. It is stated that the father and the father's mother were afflicted with a condition similar to the brother's. The patient has two normal children and one feebleminded child. This patient's serologic reaction, including a spinal fluid examination, is entirely normal. Her neurologic examination reveals an ataxic gait; she walks with a wide base; she has no cooperation for walking a straight line and on the heels and toes; Fournier tests were negative. Coordination: Romberg negative; FF & FN tests fairly well done; no decomposition of movement; no asynergia; no adiadokocinesis. Abnormal movements: none. Reflexes: Biceps, triceps, wrist 3 plus and equal, patellars 4 plus; abdominals not elicited; Babinski present on left, questionable on right. No clonus obtained. Muscular system: a moderate amount of muscular hypertonicity is present; there are no localized atrophies and no diminution of strength in the extremities. Sensory: negative so far as could be determined. Cranial nerves: I, olfactory sense normal. II, fundi normal. III, IV, VI, eye movements normal, no nystagmus, pupils slightly irregular, react to a limited extent to light. V, weakness of mouth muscles and muscles of mastication not observable; corneal reflex present. VII, no evidence of facial paralysis. VIII, hearing normal. IX, X, pharyngeal reflex present, no paralysis of uvula. XI, able to rotate head and raise shoulders. XII, speech definitely impaired; seems unable to protrude tongue. Positive neurologic findings: 1. Muscular hypertonicity with increased deep reflexes. 2. Babinski, absent abdominals. 3. Ataxic gait. 4. Pronounced speech defect. 5. Emotional instability. There is nothing remarkable about the patient's mental condition except for a moderate forgetfulness and dementia. What are the diagnostic possibilities? She does not seem to fall into any of the well recognized neurologic syndromes. It seems that multiple sclerosis is a possibility, but her age and the fact that multiple sclerosis does not tend to be familial or hereditary are against this diagnosis. She does not show the typical symptoms of progressive bulbar palsy or pseudobulbar palsy. Amyotrophic lateral sclerosis, syringomyelia and spastic spinal paralysis can be ruled out. She does not have a cerebellar syndrome. Any suggestions that you may have as to the diagnosis will be appreciated.

M.D., Ohio.

ANSWER.—In this case the dysarthria without loss of pharyngeal reflexes would seem to justify classifying the syndrome in the general category of pseudobulbar palsy. The dysarthria is undoubtedly due to bilateral supranuclear lesions of the lower cranial nerves. Such lesions often interrupt corticospinal and cerebellar pathways also, producing unilateral and bilateral rigidity and ataxia. Disturbances of emotional expression are usually present if the degeneration is widespread and are attributed to lesions of the thalamus. Such a syndrome may be produced by a number of destructive processes, of which arteriosclerosis is the most common and seems the most likely in this instance. What is extremely unusual is the familial incidence. A cursory examination of the literature has not revealed any similar groups of cases.

TOXICITY OF ISOPROPYL ALCOHOL

To the Editor:—Can isopropyl alcohol be injected in small amounts intravenously and not be toxic? I understand that when used in 98 per cent strength this alcohol is as antiseptic as 70 per cent ethyl alcohol. The reason the question is asked is that I give intravenous injections of different drugs in which I have used ethyl alcohol to sterilize the syringes and needles. I have never been concerned with the small amount of ethyl alcohol that might cling to the needle or syringe and be injected. Can I use isopropyl alcohol in the same manner?

Perry Sperber, M.D., Providence, R. I.

ANSWER.—Since no specific information on this question could be found in published literature, some animal experiments were undertaken with the following results. Isopropyl alcohol differs from ethyl alcohol in that the bactericidal effects of the former increase steadily as its concentration approaches 100 per cent, whereas the maximal bactericidal strength of ethyl alcohol is 70 per cent by weight (Price, P. B.: Ethyl Alcohol as a Germicide, *Arch. Surg.* **38**:528 [March] 1939). In vitro, pure (99 per cent) isopropyl alcohol is a strong precipitant of plasma protein, its coagulating effect being greater than that of 95 per cent ethyl alcohol and much greater than that of 70 per cent ethyl alcohol. Dilutions of isopropyl alcohol as weak as 20 per cent cause perceptible clouding of plasma. Even small amounts of pure isopropyl alcohol cause prompt coagulation of tissues. Less than 0.1 cc. of isopropyl alcohol injected intradermally into a dog's abdomen produced a small area of necrosis which eventually sloughed, leaving a sluggish ulcer. Graded amounts of isopropyl alcohol, 0.2, 0.4, 0.6 and 0.8 cc., injected subcutaneously, produced deep necrosing ulcerations of graded sizes which showed relatively little progress toward healing in three weeks. Less than 0.1 cc. of the alcohol injected into the wall of the exposed femoral vein immediately produced a spot of coagulation in the wall, inviting secondary hemorrhage. When 0.5 cc. of isopropyl alcohol was injected into the femoral vein of a large dog, a clot developed in the lumen, plugging the vein; when the animal was killed half an hour later, most of the clot had disappeared and the vein was patent but the embolus could not be found. Intra-arterial injection of as little as 0.5 cc. of isopropyl alcohol caused perceptible hemolysis in the circulating blood of a large dog, but no other toxic effects were observed after injection of 2 cc. The inference to be drawn from these experiments is that isopropyl alcohol, used in the manner indicated in the query, is not without danger and is not to be recommended.

PATENT DUCTUS ARTERIOSUS

To the Editor:—In a so-called blue baby that continues to be more or less cyanotic, is it possible to determine whether the condition is due to a patent ductus arteriosus or to some other heart condition? If the ductus arteriosus is patent can a young child be operated on? What are the chances of success? What surgeons do this type of work and where are they located? As a rule is it better to have such an operation done when the child is a few months old or to wait longer? What are the chances of such an infant's surviving if left alone?

Charles L. Entner, M.D., Connersville, Ind.

ANSWER.—Patent ductus arteriosus, unless complicated by other congenital cardiac lesions, rarely if ever causes cyanosis in infants. If a patent ductus arteriosus is present, a loud continuous "machinery" murmur should be audible in the second left interspace, and the diastolic blood pressure may be unusually low with a normal systolic blood pressure. The operative treatment of patent ductus arteriosus in cases uncomplicated by other congenital defects has been successful in recent years since the pioneer work of Dr. Robert Gross of the Children's Hospital in Boston. However, since cyanosis is present in the patient under consideration, there is little likelihood that an uncomplicated patent ductus arteriosus exists. Careful physical examination of the heart, x-ray examination of the chest and an electrocardiogram should help to clarify the diagnosis. The optimum time for operation seems to be in early childhood at the age of 4 to 6 years, although ligation has been done in adult life. The average duration of life in Abbott's series of patients not operated on was twenty-four years.

HEREDITY OF ACHONDROPLASIA

To the Editor:—Recently a patient was delivered of an achondroplastic dwarf. There had been one previous pregnancy with a normal delivery and a normal child. There is no family history of achondroplastic dwarfs. What are the possibilities—and if possible the percentage chance—of the patient's having a future achondroplastic dwarf?

M.D., California.

ANSWER.—Achondroplasia may appear as a mutation in a family, there being no previous history of the condition. Usually, however, the condition is hereditary and when so it is inherited as a single mendelian dominant. Its chance of occurring increases appreciably with the increasing age of the parents. It has been reported in five generations of a Mormon family. Of 22 offspring of the first dwarf in this pedigree, by two wives, 7 individuals were affected. Six of these persons married, and of their 49 children 24 showed the trait. The normal persons in this pedigree did not give rise to any affected offspring.

The percentage chance that normal parents of an achondroplastic dwarf will have another affected child cannot be stated. In general, however, the parents of a congenitally malformed child are twenty to twenty-five times more likely to give rise to another defective child than are parents all of whose children have been normally developed. Furthermore, if 2 children in a family exhibit congenital defects, there is a 50 per cent chance that the same defect will reappear in a subsequently born brother or sister.

VITAMIN E AND ARTHRITIS

To the Editor:—What therapeutic value has vitamin E in the treatment of fibrositis, arthritis, myositis and allied conditions?

Edwin P. Bickler, M.D., Milwaukee.

ANSWER.—As far as human beings are concerned there is no proof of value of vitamin E for these disorders at the present time.

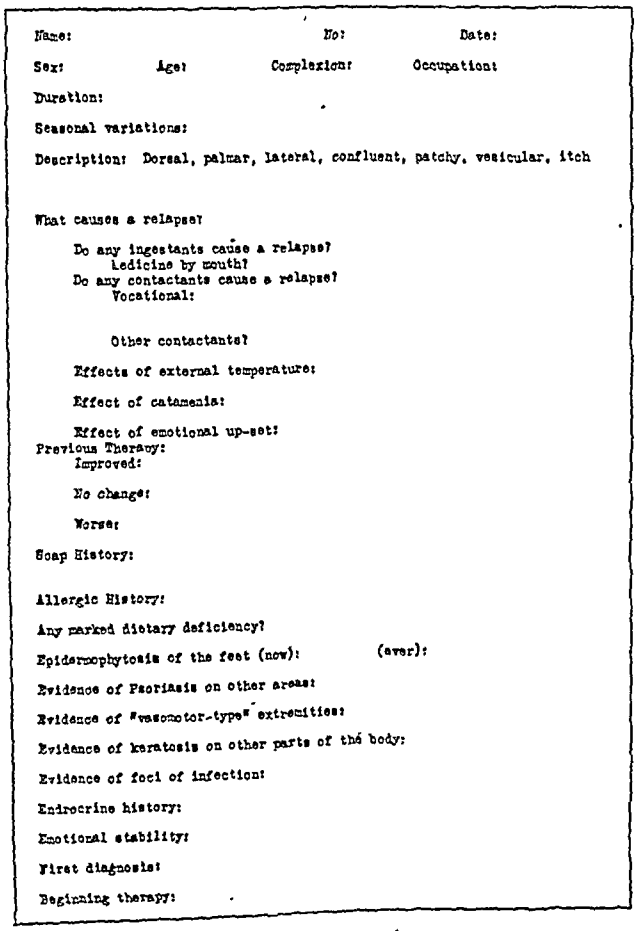
DERMATOSES OF THE HANDS

C. GUY LANE, M.D.
ETHEL M. ROCKWOOD, M.D.
CARL S. SAWYER, M.D.
AND
IRVIN H. BLANK, PH.D.
BOSTON

The various "eczematoid" dermatoses which begin on the hands and remain limited primarily to the hands and lower part of the arms constitute about 10 per cent of the cutaneous disturbances seen in private practice or a dermatologic clinic. These dermatoses as a group have been discussed and classified by Chipman,[1] Andrews and Barnes,[2] Ayres and Anderson,[3] Wise and Wolf,[4] Davidson and Birt[5] and Stokes, Lee and Johnson.[6] Single types of dermatoses belonging to this group have been investigated and frequently discussed. Engman,[7] Fordyce[8] and Sutton[9] described infectious eczematoid dermatitis. Pollitzer[10] discussed a condition which he called "recurrent eczematoid affection of the hands" and differentiated this condition from nummular eczema. Mitchell[11] emphasized the role played by streptococci in producing dermatoses of the hands. Williams[12] considered the relationship between hand dermatoses (ids) and active fungous infections of the feet. Barber[13] described a pustular dermatosis which he called pustular psoriasis. Andrews and Machacek[14] also described a pustular dermatosis but associated this disturbance with a bacterial infection of some organ other than the skin and called the cutaneous disturbance pustular bacterid. Jordan, Dolce and Osborne[15] discussed housewives' eczema. Goldman[16] made an interesting study of autonomic nervous system reactions in cheiropompholyx. Epstein[17] reported on the direct fungous infections of the hands. Gross[18] used vitamin A in the treatment of nummular eczema. Hopkins and Burky[19] have discussed autosensitization as a causal factor in chronic eczemas of the hands.

In spite of this extensive investigation no agreement now exists as to nomenclature, etiology or therapy of these "eczematoid" dermatoses. Is it not true that a patient will have a dermatosis of the hands which will be called contact dermatitis of unknown etiology by one dermatologist and dermatomycosis by another, or cheiropompholyx by one and dermatophytid by another? The clinical appearances of nummular eczema—a good descriptive term—and infectious eczematoid dermatitis are not easily distinguished. The terms pustular psoriasis and pustular bacterid may apply to the same clinical entity, but both terminologies are still used by the dermatologists. Only for specific acquired hypersensitivity and dermatomycosis has the etiology positively been established. A good response to one type of therapy may be obtained by one dermatologist while the same therapy fails when used by another.

Three years ago it was decided to study this group of patients. Since that time we have examined 475 patients, nearly all new patients and constituting about 9 per cent of the total new patients of the clinic. They included practically all of the new patients with "eczematoid" dermatoses of the hands admitted to this clinic. Three hundred and ten of these cases have been seen on three or more occasions.



This study differs from previous investigations in the following ways: All of the data reported here were obtained specifically for this study, i. e. no recorded data taken previous to the start of the work are included. Each patient was seen on each visit by one of us (I. H. B.) and by one of the other authors. In over 90 per cent of the cases the original therapy consisted only of boric acid soaks, a soapless regimen and a mild soothing ointment, such as boric acid ointment or Lassar's paste.

We began this study with a distinct appreciation of the difficulty in making a definite diagnosis and deter-

mining the etiology in these cases. We realized the confusion existing over terms. The overemphasis on fungous etiology during the past two decades was recognized, but we expected to find cases in which a fungus was the causal agent. We expected to find specific acquired hypersensitivities or occupational dermatoses and patients for whom the use of soap was the major causal factor. The clinical observations and laboratory findings which have been obtained and which are being presented have supported none of these etiologic concepts or primary causes and have led us to search for other causal factors. We have returned to a school of thought which began nearly fifty years ago, led by Unna,[20] namely the importance of bacterial invasion as a causal factor in many of the "eczematoid"

dermatoses. It is our opinion now that many of the cutaneous disturbances of the hands which are being called dermatomycosis, dermatophytid, contact dermatitis, housewives' eczema, dermatitis due to soap, neurodermite, nummular eczema or bacterid should be more correctly called infectious eczematoid dermatitis.

DATA FROM THE PATIENTS' HISTORIES

On the patient's first visit to the clinic a complete history of his cutaneous disturbance was taken which followed the questionnaire shown in figure 1. With this questionnaire it was hoped to learn the patient's own impressions about his eruption. Unfortunately in many of the long-standing cases these impressions were appreciably colored by statements made by friends, druggists or previously consulted physicians. Nevertheless the data thus obtained are of interest.

Of the 475 patients 329 were females and 146 males. The age distribution is shown in table 1. Two hundred and thirty-nine of the patients had had an intermittent eruption for longer than one year. One patient reported having had an eruption most of the time during the past forty years. Among those who had had a dermatitis for more than one year, 94 patients thought their dermatitis was worse during cold months, 45 worse during the warm months and 92 said that they had observed no seasonal difference.

With regard to occupation there has been some selection by the admitting office of the clinic, which interviewed the patient before he was examined by a doctor. If there is some evidence that the dermatitis is of occupational origin and therefore compensable, the patient is not admitted to the clinic. Over half of our patients had frequent contact with water and an alkaline substance, usually soap. This group is shown in table 2.

CLINICAL APPEARANCE

There has been a great variation in the type, arrangement, distribution and extent of the lesions seen in these patients. Some of them showed a minimum of involvement with a few scattered vesicles on the lateral aspects of one or more fingers; others showed a generalized, erythematous, papulovesicular eruption covering almost the entire area of both hands and at times extending onto the forearms. Some patients came to the clinic during the early acute phase of their eruption, others only after the acute phase had subsided and a dry, scaly, fissured eruption remained. If the patient is in the latter phase and has lesions primarily on the palms or on the knuckles, it is difficult to distinguish an "eczematoid" dermatitis from psoriasis.

The most frequent site for the beginning of the eruption seems to be the lateral and dorsal aspects of the fingers. It may be unilateral or bilateral. It usually starts as a patchy eruption and may or may not become confluent and diffuse. One of the first symptoms is pruritus. There is usually a peripheral extension of the patches, with a tendency toward a concentration of the vesicles at the edges of the lesions. Rupture of the vesicles results in serous exudation and the formation of crusts. Pustules are infrequently seen. There may be a tendency for the center of the lesion to clear, but, with an exacerbation, vesicles again appear in the center. The lesions often extend onto the palmar aspects of the fingers and onto the thenar and hypothenar eminences and flexor surfaces of the wrists. When the lesions appear on the palms, the vesicles seem deeper and thicker walled and there is a tendency toward "undermining" at the edges of the lesions.

An erythematous, vesicular dermatitis which has been diffuse from the onset and which covers the entire dorsa of both hands and extends onto the dorsal and flexor surfaces of the wrists is less frequently seen. An eruption characterized by deep, single, thick-walled vesicles diffusely scattered over the palms is rarely seen.

Almost all the patients who had had a dermatosis for longer than a few days reported alternate relapses and remissions, a relapse often occurring before a previous eruption had entirely cleared. There was no definite periodicity in many of the patients, except perhaps in some of the females who reported relapses coincident with the menses. Sometimes relapses would occur

20. Unna, P. G.: Histopathology of the Diseases of the Skin, Edinburgh, Wm. F. Clay, 1896, pp. 190 195.

every few days; at a later time the same patient might report having had a remission lasting several weeks or months.

Relatively severe pruritus is a complaint of many of these patients. The clinical picture is frequently distorted because of pronounced excoriations. Scratching is probably an important form of minor trauma which helps to keep the infection active.

LABORATORY DATA

Microscopic examination and culture on Sabouraud's medium of scales from hand lesions were made on all patients during the early months of the study. When no pathogenic, filamentous fungus was found in the first 135 cases, we became discouraged and did not continue routine culture of hand lesions on all patients. Throughout the entire study cultures were taken in selected cases when the presence of a filamentous fungus was suspected by one of us. In only 1 case was a pathogenic fungus found by microscopic and cultural examination of the hand lesions. If we had made a thorough search for filamentous fungi on the hands of every patient at various stages of his disease, more of these patients might have been shown to have dermatomycosis, but we believe that it is a rare disease of the hands.

Reports have shown that dermatophytes can frequently be cultured from superficial scales or macerated skin between the toes even when there are no subjective symptoms. We believe that extensive hand lesions are seldom "id" reactions secondary to such minor primary fungous infection of the feet. Consequently fungus studies were made only on those patients who gave a history of periodic exacerbations of foot lesions which seemed to bear some relationship to the hand lesions. The presence of an active fungous infection of the feet was confirmed in only a few instances. There were undoubtedly more active fungous infections of the feet among these 475 patients than were found by cultural study. They were missed by not making a more intensive fungus search of all cases. Only 88 patients when asked about "athlete's foot" said that they had had such a condition in the past but had none now; 33 patients said they were having their first "attack of athlete's foot" at the time of their first visit; 35 patients said they had active lesions when seen in our clinic and had had similar lesions in the past.

During recent months about 100 of these hand lesions have been cultured on plain beef extract agar and blood agar. The lesions were sponged with 70 per cent alcohol, allowed to dry, crusts or tops of vesicles were removed with sterile forceps (pustules were avoided) and the serous exudate was transferred to the agar slants with sterile, dry swabs. A large percentage of these lesions showed an abundant growth of pure culture Staphylococcus aureus, a finding which will be discussed at greater length in a later section of this paper.

Patch tests were made primarily to learn more about the reaction of the patients' skin to soap. For this purpose the pure fatty acids commonly found in soaps and the sodium salts of these fatty acids were used. We attempted to patch test as many of the patients as would return to the clinic for this purpose, but undoubtedly the importance of the tests was stressed for those patients in whom the history seemed to indicate some relationship between the use of soap and the dermatitis. Thus, this is not an entirely unselected group of patients but is weighted in favor of those who might be expected to have soap irritable skin.

In general the results of these patch tests confirm earlier statements by Lane and Blank [21] that soap rarely produces a specific acquired hypersensitivity. We feel that although the patch test was originally intended only as a test for specific acquired hypersensitivity the results of tests on 2 individuals to a series of fatty acids and soaps may give some indication of the relative soap irritability of these 2 individuals. We plan to present this point of view with the detailed results of the patch tests in a later paper. Suffice it to say at this time that among 215 patients tested 117 seemed not to have soap irritable skins; 58 appeared to have skins which would be irritated if considerable soap was used; only 29 would have been irritated by small amounts of soap. The results were indefinite in 11 patients.

PATHOGENESIS

An analysis of the data obtained from the patients' histories and laboratory studies does not support many of the diagnoses which are most frequently made for these various "eczematoid" lesions of the hands. In an attempt to clarify the confusion existing as to etiology and diagnosis, the following hypothesis is offered as an explanation of the pathogenesis of a large proportion of these dermatoses. Before going into the details of this hypothesis we wish to comment on three diagnoses which are frequently offered for this group of cases.

TABLE 1.—*Age Distribution of All Patients*

Age, Years	Number
0 to 10	4
11 to 20	79
21 to 30	135
31 to 40	105
41 to 50	79
51 to 60	50
Over 60	23

TABLE 2.—*Occupation of Patients Who Were Frequently in Contact with Water and an Alkaline Substance*

Occupation	Number
[illegible]	207
[illegible]	18
[illegible]	11
[illegible]	9
[illegible]	8
Cement workers	3
Total	256

A large percentage of the patients who had consulted a physician before coming to our clinic reported that they had been told that their cutaneous disturbance was the "same as athlete's foot." Recent reports in the dermatologic literature and our cultural data and clinical impressions indicate, however, that dermatomycosis of the hands is rare. Also in a relatively small percentage of the cases could we get any satisfactory history of a definite relationship between lesions on the feet and lesions on the hands, and seldom could we demonstrate a fungus in the foot lesions. We believe, therefore, that only a few of the eruptions on the hands are direct fungous infections of the hand or "id" reactions to fungous infections of the feet.

Over half of the patients fall into a group in which the hands are in frequent contact with water and soap or water and some other alkali. It seems logical to us to assume that if an aqueous solution which comes in

21. Lane, C. G., and Blank, I. H.: Cutaneous Detergents, J. A. M. A. 118: 804-817 (March 7) 1942.

contact with the entire hand causes a dermatitis the lesions would be generalized over the entire area with which the solution comes in contact, with the possible exception of the palms, which have a much thicker epidermis. Contact with such solutions probably does not cause a patchy dermatitis of the dorsal surface. In over 390 patients, or 80 per cent of this group, a history was given of the dermatitis being definitely patchy at the onset and in many instances it remained patchy. The data from the soap patch tests tend to confirm the impression that soap is not the primary causal factor in many of these. It is probable, however, that soap may be an important complicating factor, as will be discussed in more detail later.

There can be no doubt that a dermatitis limited primarily to the hands may be caused by a specific acquired hypersensitivity. This is frequently seen in certain occupations. The aforementioned selection of the patients has eliminated most of these cases from this series. It is our opinion, however, that a dermatitis of the hands is often erroneously called a specific acquired hypersensitivity even after a careful search for the causative agent has failed to find one. These dermatoses are too often diagnosed as "contact dermatitis of unknown etiology." When no allergen can be found after careful search it is possible that these dermatoses are not specific acquired hypersensitivities but that they are caused by some factor other than an external contactant.

Thus, it is our opinion that direct invasion of the hands or feet by a filamentous fungus, the use of soap and water, and contact with a specific allergen are less frequent causes of this type of eruption of the hands at the time the patients present themselves to the physician than is now generally supposed. What other causes may be considered for such dermatoses?

Various other factors of interest were found in a study of these patients. Many of them gave a history of frequently having "cold, clammy" hands. For many the excitement of a visit to the doctor is sufficient to cause their hands to become cold and moist. Some have noticed that their eruption recurs when they are under an emotional strain. Many women have observed relapses at the time of menstruation, either just before or during this period. It is common for housewives to report frequent relapses when they use excess soap and water, especially during cold weather. Some relapses occur coincident with an active infection in some other body organ or tissue.

Our cultural investigations have shown an abundance of Staphylococcus aureus in many of these lesions, often when no pustules are evident. There is no reason to believe at this time that this organism is different from the staphylococcus found among the resident flora of the normal unbroken skin, though no thorough bacteriologic study has yet been made of the organisms which have been isolated. Cultures from the lesions show the staphylococcus to be present in much greater numbers than is the case when cultures are made from the normal skin. Also the cultures frequently seem to be a single type of organism; cultures from normal skin as a rule show numerous types of micro-organisms.

Thus, we have observed in these patients various factors, such as vasomotor instability and relapses with menses or with the use of excessive amounts of soap and water, which have led other investigators to refer to these cutaneous disturbances as different diseases—neurodermite, endocrine imbalance, soap dermatitis, bacterid. We have also observed that Staphylococcus aureus is frequently present in large numbers in these lesions. Instead of considering these various factors and the presence of the bacteria entirely unrelated, we believe them to be related and to be multiple causal factors of a single disease entity.

We believe that the explanation of these cases lies in the interaction of these several factors. There may develop first an eruption of the hands from any of a number of causes; it may be a true contact dermatitis, dermatomycosis, dermatophytid or other dermatosis; the skin may suffer mechanical or thermal trauma. Any one of these cutaneous disturbances, together with one or more of the following factors—excessive use of soap and water, vasomotor instability, trauma, menstruation, hot or cold weather, the presence of an infection in some other organ or tissue—alters the relationship between the host and the normal resident flora of the patient's skin. These micro-organisms of the resident flora, probably of low virulence, invade the skin. Subsequently a sensitization to some bacterial decomposition product may or may not develop. From this point the eruption progresses primarily because of the invasion of the bacteria and, even if the causal agent of the original cutaneous disturbance is withdrawn, the eruption persists and perhaps extends or even changes its character. It may become a chronic affair, recurring either because of an original initiating factor or because of bacterial invasion resulting from the alteration in the host micro-organism relationship and aided by any one factor or combination of the aforementioned factors—soap and water, vasomotor instability, trauma, menstruation, hot or cold weather and focus of infection. This hypothesis is shown diagrammatically in figure 2.

We believe that the term infectious eczematoid dermatitis applies to this group better than any other term. The name infectious eczematoid dermatitis suggested by Engman [7] has been selected because it is the only one of all the names given to the "eczematoid" dermatoses of the hands which implies a bacterial invasion of the skin. Our concept of the etiology does not differ appreciably from Engman's original concept except that we believe not only that the disease is a distinct entity developing after infection or infected trauma but that it frequently develops secondarily to some other eruption.

In the foregoing discussion of the pathogenesis of the eczematoid dermatoses of the hands, no claim is made that we are presenting a new concept. Stokes, Lee and Johnson [6] have implied similar etiology for their "contact-infective and infective-allergenic dermatitis." Hopkins and Burkey [10] have described a similar etiology without reference to possible preexisting dermatoses.

The clinical appearance of the dermatoses seen during our study has varied a great deal and many eruptions have been called infectious eczematoid dermatitis by us which would not, in all probability, be classified as such according to the present day concept of the disease. Engman,[7] however, originally described a wide variety of lesions. He said:

1. The initial and earliest lesion may be a vesicle, pustule, erythematous, scaly or crusted point or plaque.

2. The vesicles are not so closely placed and are larger than those seen in an acute symmetrical vesicular eczema.

3. There is no symmetry of arrangement of the lesions, except when thus accidentally inoculated.

4. It occurs in patches, usually not involving a large area of surface in a single patch. When the disease begins as vesicles, they soon break to form a scaly patch which extends in the usual manner. New foci may begin as a cluster of vesicles

5. The patches are circumscribed with sharply defined borders. The epidermis at the periphery is usually undermined, split up, detached or raised; the two latter events being caused by perceptible or imperceptible serous or seropurulent fluid, which may, if it contains much fibrous material, instantly form a thin ridgelike crust about the periphery, while if in larger amounts and more fluid, drops of it can be pressed out from under the raised epidermis.

6. The disease increases by peripheral extension of the patches and the formation of new ones by autoinoculation.

7. The exposed parts are most frequently affected.

8. There is no attempt at central involution.

This describes fairly well the large percentage of the hand lesions which we have placed in this group. We feel that a somewhat greater variety of lesions may be included. The lesions seen by us did not all have "sharply defined borders"; some of them showed quite indefinite scattered vesicles. The undermining of the periphery seemed to occur more frequently when the lesions were palmar than when they were dorsal. In some cases there was an "attempt at central involution." It seems probable that there is a wide variation in the clinical appearance of the lesions because of variation in cutaneous characteristics, the varying immunity of the individual and differences in the virulence of the organism. The varying responses of the skin to infections by Treponema pallidum and Mycobacterium tuberculosis form a striking parallel to the varying responses of the skin to infections by staphylococci. With further study it is probable that this large group for which we have selected the term infectious eczematoid dermatitis can be subdivided into several types.

DIAGNOSIS

We do not wish to imply that the cutaneous disturbances listed in figure 2 necessarily become infectious eczematoid dermatitis. They may remain uncomplicated by bacterial invasion, but in studying this series of cases we have been impressed by the large percentage of cases which fall in this infectious eczematoid dermatitis classification. Usually it is impossible to determine the original cause of the eruption. It is our opinion that seldom does the physician see the original cutaneous disturbance or have the opportunity of making a diagnosis in the early stages of the eruption. In only 48 of our 475 cases was the eruption of less than one month's duration when the patient made his first visit to the clinic.

A sharp distinction must be drawn between infectious eczematoid dermatitis as here described and a dermatitis with secondary infection. The accepted concept of a secondarily infected dermatitis is an infection of the underlying tissue with pustulation, edema and at times lymphangitis, lymphadenopathy and fever. The invasion of micro-organisms of low virulence in infectious eczematoid dermatitis is superficial and seldom causes pustulation, edema or fever.

We have taken the liberty of suggesting an expansion of the concept of infectious eczematoid dermatitis, a term already widely used, rather than presenting an entirely new name for this group, since simplification of nomenclature is always desirable. There has been some discussion of dermatitis repens and acrodermatitis continua as the same disease, and it seems possible that these cases may be considered as a variety of infectious eczematoid dermatitis and explained on the same basis. The term nummular eczema as a disease should probably be discontinued and used simply as a descriptive term. The diagnosis of pustular psoriasis and neurodermite usually should be reserved for cases with other manifestations of these diseases. In the interest of simplification we suggest that cheiropompholyx and dyshidrosis should be replaced by pompholyx. We have made the following diagnoses in this group of cutaneous disturbances of the hands and have listed them in the approximate order of frequency of occurrence.

1. Infectious eczematoid dermatitis.
2. Contact dermatitis:
   (*a*) Nonspecific acquired hypersensitivity.
   (*b*) Specific acquired hypersensitivity.
3. Dermatophytid.
4. Bacterid.
5. Psoriasis.
6. Atopic dermatitis.
7. Pompholyx.
8. Dietary insufficiency.
9. Dermatomycosis.

An example of nonspecific acquired hypersensitivity would be a dermatitis due to soap. Dermatophytid applies to those patients who have a proved active

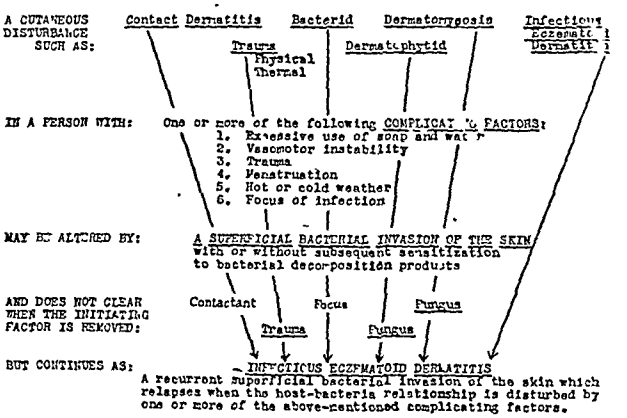

Fig. 2.—Diagram of hypothesis.

fungous infection on some area of skin other than the hands and whose hand lesions show a remission subsequent to a remission of the active fungous infection. Bacterid is similarly retained for patients with a known focus of infection but little or no direct bacterial invasion of the skin of the hands. Pompholyx implies deep, single, thick-walled, sago-grain vesicles uniformly scattered over hyperhidrotic palms, which often involute without desquamating. Pellagra is an example of dietary insufficiency. Dermatomycosis applies only to cases in which active infection of the hands by a filamentous fungus can be proved.

THERAPY

Many of the persons visiting our clinic for the first time present a superimposed dermatitis caused by self-chosen or druggist or physician recommended therapy. Most patients believe their dermatitis to be "athlete's foot" and have applied strong, irritating fungicides. Many others have been told that soap and water is bad for their hands and have faithfully avoided all contact with water, including any type of therapy employing aqueous solutions (soaks or compresses). If these dermatoses are thought to be of contact origin, much time and effort are often wasted in an unsuccessful hunt for the contactant.

In over 90 per cent of our cases the initial therapy consisted of boric acid soaks or compresses during the acute phase and a mild lubricating ointment such as boric acid ointment or Lassar's paste during the dry, fissured, desquamating phase. Boric acid soaks have proved as efficacious as potassium permanganate or Burow's solution. A soapless regimen was recommended whenever possible because it is felt that soap is an added irritant and that it predisposes to further bacterial invasion. The response to such therapy when conscientiously carried out by the patients is satisfactory in a large majority of the cases. It is not doubted that other similar mild antiseptic therapy will accomplish the same purpose.

Such mild therapy does not prevent recurrences. According to our hypothesis there is a recurrence when the host-micro-organism relationship is so changed as to permit a reinvasion of the skin by the micro-organisms. This may occur if the immunity of the host is lowered or if the micro-organisms become more invasive. If the host has been sensitized by earlier therapy or as a result of a previous infection, the clinical course of the recurrence may differ from the course of a reinfection in a nonsensitized host. Prevention of a recurrence might be accomplished either by making the micro-organism less invasive or by increasing the resistance of the host.

Attempts at alteration of the micro-organism by local application of various types of bactericides and bacteriostatic agents, including the sulfonamide drugs, have not been encouraging.

Changes in the host have been attempted along several lines. Systemic administration of sulfonamide drugs and injections of staphylococcus toxoid have been occasionally satisfactory, though they often fail to prevent recurrences. Elimination of a focal infection occasionally proves helpful. Results from the alterations of vasomotor reactions by use of such vasodilators as nicotinic acid have not been encouraging up to now. No attempts at endocrine therapy have been made. We do not yet know a satisfactory method for preventing recurrences.

Bacteriologic studies of the micro-organisms are continuing. Further studies in the elimination of various factors which may predispose to bacterial invasion are in progress. Alteration of the host-micro-organism relationship seems to offer more promise for preventing recurrences than does any form of local therapy.

SUMMARY

1. Four hundred and seventy-five cases of "eczematoid" dermatoses of the hands have been surveyed in the last three years.

2. In very few of the cases was it possible to confirm the diagnosis of dermatomycosis, dermatophytid, contact dermatitis or soap dermatitis.

3. A large number of these patients have shown recurrent attacks of a papular, vesicular and crusted eruption, limited primarily to the hands.

4. The following hypothesis is presented as an explanation of the pathogenesis of the disease entity appearing in this group of patients:

(*a*) There are various inciting factors.

(*b*) There may be several complicating factors: excessive soap and water, vasomotor instability, trauma, menstruation, hot or cold weather or focus of infection.

(*c*) There occurs an alteration of host-bacteria relationship.

(*d*) There may be a superficial bacterial invasion of the skin, with or without sensitization.

(*e*) The inciting factor may be removed but the eruption may persist as infectious eczematoid dermatitis, a recurrent superficial invasion of the skin by bacteria of low virulence which relapses when the host-bacteria relationship is disturbed by one or more of the aforementioned complicating factors.

5. In the acute phases, mild antiseptic soaks or compresses and a soapless regimen have proved successful.

416 Marlborough Street.

ABSTRACT OF DISCUSSION

DR. JOSEPH V. KLAUDER, Philadelphia: It is difficult to express the causation of eczema in the term of a single cause. We know that the reactivity of the skin is dependent on the interrelation of many causes resulting in a common picture—eczematization. In a general way the hypothesis presented constitutes the evolution of an eczematous dermatitis. There are certain phases of the authors' hypothesis which I would like to discuss: Are their premises, from which it was concluded that infectious eczematous dermatitis was the most frequently encountered dermatitis of the hands, valid? How much significance is to be attached to the demonstration of Staphylococcus aureus? Does the failure to demonstrate fungi in one examination either by culture or by microscopic examination invalidate the diagnosis of dermatomycosis? No mention was made of mosaic fungi or of the intracutaneous test with trichophytin in the diagnosis of dermatomycosis. I see more patients with what I conceive clinically to be dermatomycosis and eczematized tinea than infectious eczematous dermatitis. Should the finding of Staphylococcus aureus invalidate the clinical concept? Does not this revert back to my original statement of how interrelated and complicated is the cause of eczema? How is an eczematous dermatitis to be visualized, classified and taught to students: as eczematization or as clinical concepts of different phases in its evolution?

DR. FRANCIS E. SENEAR, Chicago: Frequently Dr. Oliver and I see a patient who has been seen by one of our colleagues with a question as to whether or not it is an industrial dermatitis. In such instances it is usually a question as to whether it is contact dermatitis or eczematoid dermatitis. We are accustomed to call each other in without saying anything as to the question in the case. I find almost invariably that we agree with each other and do not agree with the man who previously saw the case. Now I wish that Dr. Lane had time to describe a little better just exactly the clinical characteristics of the picture which he has in mind as being explained on the basis of bacterial infection. I know that at the University of Illinois, I think perhaps as a legacy from Dr. Wile, we were for a long time accustomed to speak of many of these patients with a patchy type of dermatitis as having infectious eczematous dermatitis. I know that in another clinic in the city they were accustomed to speak of the condition as eczematoid dermatitis. Owing to the confusion with the Engman type of infectious eczematoid dermatitis, visitors in our clinic didn't know what we were talking about, or I think rather felt that we didn't know what we were talking about, in that we were not differentiating these from the Engman conception and as the term nummular eczema, though of long standing, became better recognized, we changed over to the use of that term. I feel, as does Dr. Lane, that in certain of these cases—in which the lesions are patchy, the patches are for the most part sharply circumscribed, there is great variation in the size and depth and in the type of the primary lesion, there is peripheral extension, often with central involution, partial or complete, and occasionally a tendency to undermining of the scale at the periphery of the lesion—conditions are present which can be compared to those in other dermatoses which are accepted as being definitely due to some type of local infection. We have a question of employer liability constantly with us and, as Dr. Lane has pointed out, as we all know from constant clinical experience, many of these patients, even when they get away from contact

with the primary irritant, continue to have recurrent attacks of this type of sharply defined, patchy dermatitis. The constant occurrence of certain features in these cases of acrodermatitis, some of them only in the severe types—such things as the early and severe involvement of the nail, the changes in the finger tips to produce conical stumps, the radiating pain, the extreme resistance to treatment, the occasional occurrence of mucous membrane lesions—would make it improbable that that particular group should be included in this suggested increased conception of infectious eczematoid dermatitis.

DR. GEORGE C. ANDREWS, New York: The study by Dr. Lane and his associates coincides closely with one which Dr. Barnes and I made about two years ago that was reported before the Southern Medical Association, and published in the *Southern Medical Journal* in December 1941. We analyzed a series of 200 cases of recalcitrant pustular and vesicular eruptions of the palms and soles. The only difference between their statistics and ours is that they took 500 consecutive cases whereas we took only those recalcitrant cases which we saw for as many as ten or more visits. We did not take the simple cases. We ended up by finding that in 36 per cent of our cases we could not find the cause, no matter how we studied them or what we did. In our series we found that only 25 per cent of these cases were positive for fungi on the feet. There were only 5 per cent with fungous infections of the hands. We found that about 8 per cent were what we considered bacterial infections of the hands. I agree with Dr. Lane on the importance of nervousness and of various emotional strains in these conditions. Our feelings are like Dr. Lane's concerning complications. We often have cases which start as one thing and then develop a secondary bacterial infection or some other sensitization. The importance of cultures showing large amounts of hemolytic staphylococci is rightly stressed. I have found it best in some cases to give moderate doses of sulfadiazine. I usually give 2 Gm. a day for four days. It is surprising how many will clear up completely of their trouble. Of course, some do not, but it certainly shows the importance of secondary bacterial infection in these conditions. I believe some of these patients develop a sensitization to our remedies, simple remedies, which lead to the persistence of the trouble, and that also must be considered.

DR. LLOYD W. KETRON, Baltimore: Every effort should be made to classify eruptions on the hands as manifestations of one of the common diseases before attempting to create a new dermatosis which limits itself to this particular portion of the body. Those of us who have practiced a great many years have frequently seen patients with dry or vesicular eruptions on the fingers and hands that were difficult to classify. Some of these patients later returned with eczematous eruptions on other portions of the body, such as seborrheic dermatitis, which would make one feel that perhaps the rash on the hands had been a manifestation of this disease. Some diseases do tend to limit their activities to certain parts of the body, but most of them may at times occur at almost any place; for example, such disorders as lupus erythematosus, which particularly involves the face, may at times affect the hands, and I am sure that if it should occur in this location alone, diagnosis would be quite difficult.

COMMANDER MARION B. SULZBERGER (MC), U.S.N.R.: It is easy to confuse different dermatologic entities with one another when they occur on the hands. This is probably because there is something about the site, and the trauma and exposures of the site, and the anatomic and physiologic relationships in that site which cause the different eruptions to resemble one another. Nevertheless, if one takes 100 cases, I believe that one can, with a fair amount of care and skill and experience, cull out some of them. When all the certain diagnoses have been established there always remains a large residual group of undiagnosed cases. And what are all these—these which we variously call eczematoid dermatitis or dermatophytid or dyshidrosis or eczema? Most of those terms don't mean anything to me. We do know that they are almost all made worse by certain things. The picture is one of a vesicular dermatitis or a vesiculopustular and papular dermatitis which is often chronically recurrent and which is generally made worse by different "trigger" factors, including physical factors (heat, cold, moisture), nervous and emotional upsets, the presence of distant foci of infection of the skin or elsewhere (particularly the tonsils), occasionally by certain foods or drugs; a dermatosis which is often irritated by local effects of agents from the outer world (soap-caustics and allergens, micro-organisms and the like). I would like to suggest consideration of the possibility of a virus, herpetic virus, which is notoriously activated by the mentioned trigger factors. This possibility should be strongly considered in relation to nummular eczema. In undiagnosed recurrent vesicular eruptions of the hands it might be fruitful to investigate carefully in the direction of possible herpetic infection. Perhaps the results would account for at least some of the cases. However, I am convinced that many of these cases are of composite etiology, in which there are many links to the chain of the causation; and for this reason sometimes cure can be effected and the chain can be broken by simply striking out one of the links of the chain of causes.

DR. C. GUY LANE, Boston: Perhaps we have not made much progress with the condition, but I do hope that by continually discussing it we shall progress and do something for persons who have this recurrent papular, vesicular and pustular dermatitis of the hands. These cases which we have been studying have probably been more or less unconsciously selected. For example, in our hospital anything which seems to be an occupational case is picked out at the admitting office and is referred to one of the younger men on the staff, so that we rarely get them in the clinic unless they have been passed by the admitting office. There has been an unconscious selection with regard to soap cases because Dr. Blank and I have been interested in these detergents and I think we have been more apt to lay disturbances to soap perhaps than is justifiable. There may be also an unconscious selection in regard to some of the fungous cases. Some of the acute contact dermatitis cases have undoubtedly been assigned to other staff physicians rather than to some one of the four authors. There has been a great variation in clinical appearance. We have no way at the present time of standardizing the clinical picture of this group, but I believe that perhaps we can pick out certain types and classify them later on. We can only suggest grouping them under some such heading as infectious eczematoid dermatitis and then perhaps later on divide them into several classes or types. I agree with Dr. Klauder that our diagnosis of fungous infections of the hands should be limited to those cases in which we have definite microscopic or cultural evidence. I think in that general the same thing is true with regard to the specific acquired hypersensitivity, namely, that we need to prove them. I agree with Dr. Andrews that at least in 36 per cent of our cases the cause was not known. We have suggested the hypothesis to explain some of these cases. There are undoubtedly more complicating factors than were listed under the heading of complicating factors. We inserted in the chart those few items, but I believe that there are probably a large number of others which can act as the trigger mechanism in disturbing the host bacteria relationship.

The Cornerstone of Modern Medicine.—The first man who really knew the human body in an exact and complete fashion was Andreas Vesalius. Truly the foundation of modern medicine was his great seven volume work "The Anatomy of the Human Body" ("De Humani Corporis Fabrica"), first published in 1543, the same year that greeted Copernicus' "Revolutions of the Heavenly Bodies." Vesalius was born in Brussels; studied—with dissatisfaction, as he relates in the introduction to "The Anatomy" given here—at Paris; became professor of anatomy at Padua, where he observed with his own eyes and dissected with his own hand, sometimes—tradition says—getting material by cutting down from their gibbets the hanged bodies of condemned criminals. The opposition of authorities, chiefly ecclesiastical, eventually drove him to Spain, where he served the Emperor Charles V, to whom "The Anatomy" is dedicated. —The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

CARBON TETRACHLORIDE POISONING

A PRELIMINARY REPORT ON THE USE OF METHIONINE IN HEPATITIS

JAMES H. EDDY JR., M.D.
SHREVEPORT, LA.

A recent experience with carbon tetrachloride gave me the opportunity to make use of methionine as a therapeutic aid. The value of this drug has been suggested by animal experiments reported by György [1] and by Miller and Whipple.[2] The first clinical use was reported by Beattie and his associates,[3] who described its use in a case of carbon tetrachloride poisoning. This paper was discussed in an editorial [4] in THE JOURNAL. I believe that this has been the first opportunity to treat a group of cases of acute hepatitis with methionine in this country. It is felt that in the first case death was very likely and that methionine should be considered as having been instrumental in the recovery of the patient.

Carbon tetrachloride has been well known as a toxic chemical for many years but there has been a tendency to treat its dangerous properties somewhat lightly. I believe that the occasional report of cases such as this are valuable in that they serve to remind us of the danger of some of our everyday chemicals.

Carbon tetrachloride is capable of producing toxic results through skin absorption, through ingestion and by inhalation of the vapor. The mode of entrance of the drug appears to have little to do with the results produced except that the acute poisoning is almost always due to ingestion or to the breathing of an atmosphere highly contaminated by the vapor. The patients who were the subject of this report were employed at an operation where rags were saturated with carbon tetrachloride and were wiped over a hot land mine. The mine was hot enough to vaporize the carbon tetrachloride immediately. There was not sufficient heat to produce phosgene. The operation moved fast so that a tremendous amount of the chemical was vaporized in a closed room having no mechanical ventilation. Unfortunately no exact measurement of the concentration of the vapor is available. It is known, however, that the concentration of acetone under similar conditions was over 2,000 parts per million. This serves to give some indication of the exposure but is less than was present in the carbon tetrachloride. These people were exposed for from one to two hours. The highest concentrations permissible in workrooms are usually given as from 50 to 100 parts per million. A delayed fatal type of poisoning with death in from one to two weeks was described by Schutz [5] following a single inhalation of high concentrations. He mentioned the symptoms of nausea, headache, vomiting, fever, cramping, unconsciousness, cyanosis, jaundice, dyspnea and coma, all of which were seen in 1 or more of these patients.

In all of my cases there were early symptoms during the time of exposure, but none of these were very severe and all of the employees worked about six hours after the exposure. They all returned to their homes at the end of the shift. The early symptoms were described as a sense of drunkenness, as if too much alcohol had been ingested. There was a sense of faintness, dizziness, headache, nausea and vomiting, cough, and cramping pain in the abdomen; all the patients complained of a very unpleasant odor. Most of them went to the first aid station during the shift, where they took an alkali, and only 1 felt bad enough to lie down for an hour or two. All the patients went to the door after a short exposure, as they had a desire to "get some fresh air." After they returned to their homes they began feeling much worse on the following day, and nausea and vomiting were the principal symptoms. Visual disturbance as described by Wirtschafter [6] was not found. There were some who had attacks of dizziness and weakness, and 2 patients said that they lost consciousness for short periods. One patient became much worse on the fourth day after exposure and was taken to a local hospital, where she died within a few hours. It was stated that she became dyspneic and died from respiratory embarrassment. She had a good urinary output during her illness, and a urinalysis done shortly before death showed no evidence of kidney damage. Autopsy was done but not all of the organs were examined. Unfortunately sections of the kidney were not submitted to the pathologist. The liver was reported as being extremely large, but the weight was not given. Examination of the sections was reported by Dr. W. R. Mathews of the Shreveport Charity Hospital as follows:

> The sections of the liver show almost total necrosis. The process is uniformly central, extending out from the central veins in a uniform fashion finally to involve all of the lobule except a thin zone of cells at the periphery. Even the latter show severe degenerative change, characterized by vacuolation and increased granularity of the cytoplasm and pyknosis and karyolysis of the nuclei in many instances. In the central necrotic areas, involving most and occasionally all of every lobule, only the débris of necrotic liver cells, Kupffer's cells, blood and the scaffolding element of the hepatic parenchyma remains. No evidence of regeneration of bile ducts or hepatic cells is present, nor is there any cellular inflammatory reaction. The occasional leukocyte noted in the necrotic areas is not more than would be expected to be present in the blood. The lymphocytic infiltration in the portal canals is not more than one sees routinely in sections of the liver and may be assumed to have been present prior to the onset of the acute necrosis.

Another patient had the usual early symptoms but was well enough to return to work on the following day. She continued at work for about one week, after which she remained at home and was not seen by a physician until she developed a fatal pulmonary hemorrhage at the end of fourteen days after exposure. Again the autopsy was only partial and was done after the body had been embalmed for four or five days. No petechiae were seen, and there was no jaundice. There were no pleural adhesions, and the cut section of the lung showed no gross cause for her fatal hemorrhage. Examination of the heart and aorta was not made.

The stomach contained no blood, and there was no gross change in the stomach or intestine. The liver was slightly enlarged and showed a mottled yellow surface. The sections were reported by Dr. Mathews as follows:

Sections of the liver show diffuse central necrosis that involves from one third to a half or more of the lobule. Not infrequently the process in adjacent lobules meets, and occasionally a small area of liver cells shows complete encirclement of what appears chiefly to be collapsed stromal element. In such areas a few fibroblasts may be present, and the same holds true for an occasional central area; but this change certainly is not conspicuous. A fair number of lymphocytes and a few polymorphonuclear leukocytes are present in the necrotic area. Immediately surrounding the central veins a fairly thick zone of collagenous connective tissue is noted, which represents condensation of this element normally present rather than productive reaction. The hepatic cells remaining show pronounced degenerative change. The cytoplasm is vacuolated and granular and the nuclei stain poorly and frequently not at all. Colonies of bacteria, exciting no inflammatory reaction, are sparsely scattered throughout the section. There is no evidence of bile duct regeneration.

The kidneys were enlarged but the weight was not given. The sections were described as follows:

There is acute diffuse pyelonephritis characterized by small cortical abscesses, more or less focal acute cellular inflammatory reaction not yet developed to abscess stage, involving glomeruli, tubules and interstitial tissue; and accumulation of pus in dilated tubules which usually show atrophy or loss of lining cells. There is also diffuse congestion, interstitial edema and severe degenerative changes in the tubular epithelium. None of the sections available for study show the pelvic lining. Gram's stain reveals small and large colonies of negative bacilli, which apparently vary rather widely in size. Some are slender, resembling colon bacilli, while others are thick and attain considerable length or are short and plump. The presence of such colonies of bacteria in the midst of the abscesses and cellular inflammatory reaction is interpreted as evidence of etiologic significance.

The findings indicate the expected change in the liver following carbon tetrachloride exposure. Whether or not this damage precipitated the infectious process in the kidney and what it had to do with the pulmonary hemorrhage is open to conjecture. It is known that a few months prior to her illness the patient was reported as having a loud blowing systolic murmur over the whole precordium.

Six other patients were seen at this hospital. These had icterus indexes from 2.7 to 285 on admission. The most seriously ill patient had an icterus index that reached 344. She was extremely ill and her liver was felt four fingerbreadths below the umbilicus. The liver was soft and tender. She received 68 Gm. of methionine during her hospitalization, and it is believed that this was the most important factor in the outcome. All of these patients were given methionine as well as intravenous glucose solution and were fed a high protein, high carbohydrate, low fat diet, which was given through an indwelling duodenal tube. A mixture of milk (3,000 cc.), powdered skimmed milk (180 Gm.), banana powder (150 Gm.), sugar (300 Gm.), cod liver oil (30 cc.) and brewers' yeast (12 tablets) was suggested and was used. This was given in equally divided portions every two to three hours through a duodenal tube. After twenty-four hours of this mixture all of the patients developed a troublesome diarrhea. The mixture was stopped and paregoric relieved the diarrhea. These patients demonstrated some evidence of kidney damage and in case 2 the nonprotein nitrogen reached 377.8 mg. per hundred cubic centimeters. This patient had generalized edema, oliguria and convulsions, and her urinalysis revealed albumin, red cells and casts. Thirty days after exposure the nonprotein nitrogen had returned to 33 mg. per hundred cubic centimeters and there were no symptoms except poor vision in the right eye. Ophthalmic examination showed no retinal pathologic condition. The laboratory examinations in this group are summarized in the accompanying table. The histories of the 2 patients showing the typical pictures of kidney and liver involvement are summarized:

REPORT OF CASES

CASE 1.—L. J., a Negro woman aged 38, was engaged in cleaning land mines on the night of Nov. 30, 1944, when carbon tetrachloride was introduced into the operation. The patient continued at her work for about one hour but stated that she began feeling dizzy and nauseated shortly after she began using the material. She went to the first aid station, where she was given an alkali, and she then returned to her work and completed the shift. She stayed at her home until December 5. During that time she was nauseated and vomited frequently. She stated that she frequently lost consciousness for short periods. There was also dizziness and headaches,

Laboratory Examinations

Case No.	Icterus Index	Hanger Cephalin Flocculation Test	Blood Nonprotein Nitrogen	Urinary Bile	Urinary Casts	Urinary White Cells per H. P. Field	Urinary Red Cells per H. P. Field	Urinary Albumin
1	344	++++	63.8	++++	++	10-12	1-3	+++
2	16.6	++++	377.8	+	++++	15-20	125-150	++++
3	8.4	+++	.....	0	0	0	0	0
4	20.0	++++	133.6	0	+++	12-15	8-10	++
5	8.4	+++	41.4	Trace	0	2-5	Occ.	0
6	4.6	+++	31.6	0	0	Occ.	0	0

and later the patient became irrational. On December 5 she was seen by her family physician, who sent her to this hospital.

On admission the patient was deeply jaundiced and extremely dehydrated. She vomited almost continuously, was alternately talking at random and comatose, and in general appeared to be at the point of death. Her mucous membranes were pale and quite yellow. The liver was felt four fingerbreadths below the umbilicus and was soft and tender.

Treatment with intravenous glucose solution was begun immediately. An indwelling duodenal tube was passed and a diet having a high protein, high carbohydrate and low fat content was given by tube every few hours. Methionine in doses of 2 Gm. was given every four hours.

On admission the urinalysis showed a 3 plus test for albumin, a decreased urobilinogen, 4 plus bile and an occasional red and white cell but no casts. Examination of the peripheral blood showed 2,430,000 red cells, with 8 Gm. of hemoglobin. The total white cell count was 18,400, and the differential revealed 27 degenerated polymorphonuclears, 5 band cells, 58 segmented polymorphonuclears, 5 lymphocytes, 1 eosinophil, 1 basophil and 3 monocytes. Three normoblasts were seen per hundred white cells. There were moderate anisocytosis and slight diffuse polychromatophilia. The platelet count was 236,000. The icterus index was 285.6. Two days later the icterus index reached 344.7. A Hanger cephalin flocculation test was 4 plus in twenty-four hours.

The patient remained weak and complained of shortness of breath, a smothering sensation and a sense of tightness in the chest. This was believed to be due to her anemia, and a transfusion of whole blood was given. She continued to improve rapidly after that, and on December 9 her icterus index was 117. By December 21, or sixteen days after admission to the hospital, the icterus index was 33. The size of the liver

decreased rapidly during the time she showed her clinical improvement, so that by the time she left the hospital on December 21 the liver edge could be felt about 1 cm. below the rib cage. Her urinary output was good during the course of her hospital stay, but on December 14 the nonprotein nitrogen was 68.8 mg. per hundred cubic centimeters. This value returned to normal by the time of discharge. The urine showed many casts during hospitalization but returned to normal in the following weeks. On Jan. 16, 1945 the icterus index was 11.3 and the patient was feeling quite well. It is interesting to note that the Hanger flocculation test returned to normal on this same date.

What the picture holds for this woman is open to question. With the tremendous amount of damage that she must have had it is not too unlikely that a toxic cirrhosis may develop.

CASE 2.—A Negro woman aged 30, obese, gave a history of early symptoms and working conditions parallel to that of case 1. She stated that she vomited every time she took food or drink. She saw her family doctor on Dec. 3, 1944, who advised rest and a diet. On December 5 she was brought to this hospital. She was quite dehydrated, and there was some edema of the eyelids. There was a yellow tinge to the scleras, and the liver edge was palpable about 3 cm. below the rib margin. Vomiting was almost continuous, and the patient complained of cramping abdominal pain.

The Hanger cephalin flocculation test was 4 plus and the icterus index was 16.8 There were 3,910,000 red cells, with 13.3 Gm. of hemoglobin. The white cell count was 10,200 and the differential count was 75 polymorphonuclears, 20 lymphocytes, 2 eosinophils, 2 basophils and 1 monocyte. There was slight anisocytosis and poikilocytosis but no polychromatophilia. The platelet count was 282,000.

The treatment consisted of intravenous glucose, diet similar to case 1 and methionine. Early in her disease our supply of methionine was low and all of it was being given to patient 1. During that period Stearn's amino acid preparation was given to the patient in 50 cc. doses every four hours.

Vomiting and diarrhea were troublesome during the patient's entire illness. The urinary output was scanty, but unfortunately her intake and output of fluids were not recorded. The edema of her face became more prominent and on her fourth hospital day she complained of more abdominal cramping, severe headache and persistent hiccup. The following day she had two convulsions and complained of headache and blurring of vision. She had an incontinence of urine and feces and the following day had two more convulsions. Treatment at this time consisted of intravenous hypertonic glucose and sedation. The blood pressure at this time was 160/106. The blood nonprotein nitrogen was 377.8 mg. per hundred cubic centimeters and the urinalysis showed many red and white cells, casts and 4 plus albumin. Her urinary output increased following this episode and exceeded the intake for the next week. She felt better and her nonprotein nitrogen was 33.2 mg. per hundred cubic centimeters on Jan. 1, 1945. Her icterus index in the meantime had returned to 5.4. The patient has continued to improve and at present shows no evidence of her illness except some blurring of vision in the right eye.

COMMENT

There were no untoward reactions to methionine in this group, and the only indication we had for stopping the drug was recovery of the patients.

The pronounced difference in susceptibility to carbon tetrachloride seen in this group is interesting, as all of the patients had about the same exposure. In this connection it should be pointed out that all of the patients were Negroes who lived in a rural community. These people are known to eat a protein deficient diet and one that is usually high in fats. Likewise the occasional case of fatal poisoning by a relatively small amount of carbon tetrachloride is probably best explained on the basis of nutritional deficiency, particularly of certain proteins. This is suggested by the case reported by Horrocks [7] of a Filipino boy aged 8 years who was said to live on a diet consisting mainly of rice and who had a fatal termination after ingestion of only 0.431 cc. of carbon tetrachloride.

The effect of certain proteins in preventing liver damage has been shown conclusively to depend on the presence of methionine or cystine. When cystine is present in the absence of methionine it is necessary that choline also be present in the diet. This has led György [1] to suggest that choline and cystine are necessary for the synthesis of a third substance which is possibly methionine. Cystine or choline alone was unable to prevent the development of hepatic damage in György's animals. Cystine without choline or methionine is said by György to aggravate a cirrhosis, and the administration of large doses of cystine may in a short time produce liver necrosis and a cirrhosis of the Laënnec type.

Most of the reports concern the use of these dietary factors in the prevention of liver damage and little thought has been given to their use as therapeutic aids once the damage has been done. Miller and Whipple [8] gave methionine to dogs after exposure to chloroform and found that they could be protected up to four hours after exposure. As noted by György,[1] their experimental conditions were especially severe.

It is possible also to theorize on the likelihood of a dietary factor influencing the production of the tubular necrosis of the kidney seen in these cases of carbon tetrachloride poisoning as well as that seen in the so-called hepatorenal syndrome of other diseases. György [1] mentions milder forms of necrotizing nephrosis in combination with hepatic necrosis which were produced simultaneously in animals by purely dietary means. This does not, however, help to explain why one person demonstrates the predominantly renal syndrome and another shows the greatest pathologic change in the liver.

The results in this small group of cases are at least suggestive of the clinical value of methionine in certain types of liver damage. We have also treated a rather large number of patients having trinitrotoluene hepatitis with methionine and are encouraged to find no fatalities in this group. One patient with epidemic hepatitis was given methionine, and it was felt that improvement began soon after administration of the drug.

The United States Public Health Service [9] reports the use of methionine in protecting weanling rats maintained on a protein deficient diet against otherwise severely intoxicating doses of dichloroethane.

We believe that these clinical findings offer support to the experimental work concerning the importance of certain dietary factors in the prevention and treatment of liver damage. Much more detailed clinical work is necessary before the last word can be said about the value of methionine in liver disease. It is hoped that this work will prompt other clinicians to report their observations concerning methionine.

ACUTE INFECTIOUS HEPATITIS IN THE MEDITERRANEAN THEATER

INCLUDING ACUTE HEPATITIS WITHOUT JAUNDICE

COLONEL M. HERBERT BARKER
MEDICAL CORPS, ARMY OF THE UNITED STATES
MAJOR RICHARD B CAPPS
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
MAJOR FRANK W ALLEN
SANITARY CORPS, ARMY OF THE UNITED STATES

For many years prior to this war infectious hepatitis was considered to be a relatively infrequent and unimportant disease. During the last four years, however, cases have been appearing in increasing numbers in both civilians [1] and military personnel in various parts of the world. This has afforded opportunity for the study of large groups of cases and has led to a reawakening of interest in the disease among both investigators and clinicians.

Our own interest in this condition began in 1942 when two of us (M. H. B. and R. B. C.) participated [2] in an official investigation of the so-called "postvaccinal" hepatitis at Fort Custer, Michigan. At that time an extensive clinical and laboratory study was carried out on over 2,000 individuals who were recipients of yellow fever vaccine, 700 of whom were hospitalized with jaundice. This experience subsequently proved most valuable when we were given the opportunity of observing infectious hepatitis occurring in the Mediterranean theater.

Beginning in February 1944 we conducted an organized study of the disease as it occurred in our troops in the Mediterranean theater. From this work it has become apparent that many of our older concepts, especially regarding diagnosis, duration and treatment, must be altered. In view of the increasing frequency of various forms of the disease in this country, both among civilians and among military personnel, it is pertinent at this time to present some of our findings.

MATERIAL

As a result of the foresight of the Surgeon's office, Mediterranean Theater of Operations, a broad program was instituted for the investigation of hepatitis. Observations from all parts of the theater and on various aspects of the disease were correlated and integrated from a central office. This involved the cooperative efforts of many individuals, to whom much credit is due. As the nucleus of the program an intensive clinical and laboratory study of the problem was conducted by us in a group of hospitals located close to special laboratory facilities. The present paper is based largely on data obtained from this source.

One thousand one hundred and seventy-two unselected cases of hepatitis were personally examined and studied between February and November 1944. Four hundred and thirty-one of these were carefully followed throughout their course until discharged from the hospital either to duty or to the United States. These cases were selected only to the extent that their hospital stay coincided with the study period.

Various control observations and special studies concerning specific aspects of the disease were carried out on other groups of cases totaling several thousand. In addition we were able to observe the disease as seen in different parts of the theater. This is of importance, since early cases tend to predominate in the forward areas whereas the chronic cases accumulate in the rear.

METHODS

The graduated exercise tolerance test consisted of a ten day program of increasing exercise beginning with a 1 mile hike on the first day and ending with a 4 mile hike, fifteen minutes of calisthenics and forty minutes of volley ball on each of the last three days. Jogging was ordered frequently during hikes, and jumping types of calisthenics were stressed. For patients who had not been in bed, only the last three days of the foregoing routine were employed. Cases were examined daily in the morning before exercise in order to note the effects of the previous day's activities. It is important to make the examinations at the same time of day, as the liver is usually larger in the afternoon than in the morning. If the liver becomes enlarged and tender the test is considered to be positive or abnormal. Where the liver is already enlarged, further increase in size may not occur but definite tenderness develops. An increase in symptoms and laboratory evidence of liver dysfunction is important and should be taken into consideration, but interpretation of the test as positive should not be made on this basis alone.

Laboratory data presented in this paper were obtained under the supervision of one of us (F. W. A.), assuring uniformity.

Sulfobromophthalein.—The 5 mg. per kilogram dose was employed. Dye retention of 3 per cent or more in one hour was considered abnormal. In addition, either a thirty or a forty-five minute sample was drawn for comparison. Visual readings were frequently checked photometrically.

Acetone Icterus Index.—The value of this method [3] lies in the elimination of hemolysis as a confusing factor. The serum is extracted with equal parts of acetone and the latter read against the usual standards. Eight or more is definitely abnormal.

Methylene Blue Urine Test.[4]—This test was performed by adding 0.25 per cent aqueous solution of methylene blue chloride to 5 cc. of urine drop by drop, employing a medicine dropper delivering 19 to 21 drops per cubic centimeter. If a green color develops and persists after the addition of 3 drops but turns to blue after 4 drops, the test is mildly positive. If the green persists after 4 drops or more it is definitely positive. Unpublished data suggest that this is a sensitive test for bilirubin, although the mechanism is not yet entirely clear. Of 1,267 normal controls, 99.1 per cent gave normal results. In the only tests over 4 drops (4 cases) jaundice developed in three days.

The Surgeon's office, Mtoupa, offered the opportunity and supplied the facilities to carry on this work. The medical officers, nurses and other military personnel made the investigation possible.

The cephalin cholesterol flocculation test was performed as described by Hanger.[5] Bodansky's [6] method was used for alkaline serum phosphatase. Standard methods were employed for routine procedures.

ETIOLOGY AND PATHOLOGY

Havens, Paul and Van Rooyen [7] have recently summarized our knowledge concerning etiology. The disease is probably caused by a filtrable virus. Oral, subcutaneous and intravenous modes of transmission have been reasonably established. Transmission by droplet infection has not been clearly proved. Although an insect vector is a possibility, as yet none has been incriminated. It is probable that in the Mediterranean theater spread of the disease has been chiefly by the enteric route. Elsewhere, pooled plasma and serum and blood transfusions may play a more important role. Inadequately disinfected needles and syringes may also be a means of transmitting the disease.

The pathologic picture as seen in fatal cases, in patients with hepatitis accidentally killed and in liver biopsies will be described elsewhere by others. Suffice it to say that the essential lesion is involvement of the

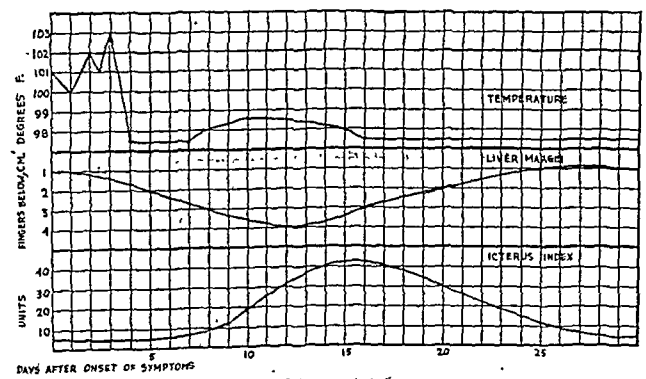

Chart 1.—Schematic representation of the course of a typical case of acute hepatitis with jaundice.

parenchymal cells of the liver, with an inflammatory exudate in the periportal areas. Lymphadenopathy is usually present.

CLINICAL PICTURE AND COURSE

It is probable that infectious hepatitis, like many virus infections, should be looked on as a systemic disease with a predilection for the liver. Thus there is evidence from various sources, clinical, pathologic and roentgenologic, suggesting involvement of the lymph glands, the bowel and the pancreas. It is quite possible that under certain circumstances many of the symptoms ordinarily attributed to the liver, such as those arising in the gastrointestinal tract, may be the result of extrahepatic lesions.

Infectious hepatitis as seen in the Mediterranean theater presents a sufficiently characteristic clinical picture, except at the onset, so that the diagnosis can usually be established by the experienced observer on purely clinical grounds. The course and severity are, however, quite variable. In the typical case there is a prodromal period of acute symptoms, without jaundice and without enlargement of the liver. This is followed by an acute icteric stage with enlargement and tenderness of the liver. Finally there is a convalescent stage with a disappearance of symptoms and jaundice and a return of the liver to normal size. Occasionally recovery is so protracted that the condition can be termed "chronic" hepatitis. By this term is meant persistence of the disease for more than three months. It is not to be inferred that the pathologic condition of the liver is permanent in nature. This important variety of the disease will be dealt with in a subsequent paper. Acute hepatitis without jaundice runs an essentially similar course but for purposes of clarity will be discussed separately.

Prodromal or Preicteric Stage.—A definite prodromal stage occurs in 83 per cent of cases of acute hepatitis with jaundice. The onset of symptoms precedes the appearance of jaundice by from one to three weeks in 50 per cent, from four to six days in 20 per cent and by three days in 13 per cent. The remaining 17 per cent cannot be said to have a definite prodromal stage, since jaundice appears within two days of onset. In general, the more serious cases fall into this last group.

The prodromal period is initiated by an acute febrile onset in well over 80 per cent of cases. The temperature is usually elevated to between 100 and 103 F. and is associated with chilly sensations, but shaking chills are rare. Characteristic symptoms are malaise, headache, lassitude, abdominal discomfort and anorexia. There may be considerable generalized muscular aching and a more severe headache than would be expected with the degree of fever. Lassitude is usually present and rather severe. The abdominal discomfort consists of mild distention, intestinal cramps associated with flatulence and right upper quadrant distress. It is very characteristic for the latter symptom to be aggravated by exercise or by jolting, as produced by a rough automobile ride. Transient loose stools frequently occur at the onset. The anorexia is usually followed by nausea and often vomiting within the first three days. Other symptoms less commonly seen are somnolence, mild rhinitis and labial herpes. Urticaria and arthralgia are rare prodromal symptoms.

Characteristically these acute symptoms last for about three or four days and are followed by a relatively symptom free and afebrile interval of five to ten days' duration. Jaundice is then ushered in by a recurrence of fever and acute symptoms. This is shown schematically in chart 1.

Physical findings during the preicteric stage of the disease are not striking and are often inconclusive. The liver is usually tender but not enlarged at the onset. Enlargement generally develops, however, prior to the appearance of jaundice. Liver tenderness is best elicited by fist percussion, using a jarring rather than a sharp blow over the right lower ribs. A small well localized dime sized (18 mm.) area of tenderness in the right costovertebral angle or in the eleventh intercostal space at the lateral border of the erector spinae muscle is also a reliable sign of liver inflammation. This is probably due (as suggested by Lieut. Col. E. C. Spalding, M. C.) to the apposition of nonperitonealized liver to the posterior abdominal wall in this region. Splenomegaly when present is most suggestive but is found in only 10 to 15 per cent of cases. One of the most constant and helpful early findings is

lymphadenopathy. Typically a soft, slightly tender, lima bean sized gland is found along the posterior border of the sternocleidomastoid muscle low in the neck.

Acute Stage With Jaundice.—As jaundice appears, or perhaps a day or two before it becomes clinically evident, there is a recurrence of fever, usually milder than at the onset. A sharp aggravation of gastrointestinal symptoms, lassitude and somnolence occurs simultaneously. In cases without a true prodromal period this constitutes the onset of the disease. Occasionally the onset is insidious and practically afebrile to the extent that jaundice is the first evidence of illness.

An important finding that may be seen at this stage is right upper or right lower abdominal pain with associated tenderness and spasm of the abdominal wall simulating an acute condition of the abdomen. Such cases may mistakenly lead to operation for acute appendicitis, acute cholecystitis or even ruptured peptic ulcer. The diagnosis is particularly difficult in cases in which jaundice has not yet appeared. Suspicion should be aroused by a large and tender liver, which is almost invariably present.

During this period of rising icterus the patient is quite uncomfortable and unhappy. Nausea and abdominal discomfort are much in evidence. Clay colored stools and pruritus are unusual. Characteristically the maximum elevation of icterus is reached quickly in from three to seven days, and coincidentally the fever abates and abrupt symptomatic improvement occurs. The reappearance of appetite and the improvement in general sense of well being is especially striking.

Shortly after reaching a maximum, the icteric level begins to decrease. The duration of this defervescent period is variable, depending particularly on the maximum height of the icterus, the type of treatment employed and the fluid intake. In a general way it provides an index of the rate of recovery from the disease. The usual total duration of jaundice is between two and four weeks but may vary from a few days to three months or more. Symptoms during this period consist of gas, intestinal cramps, intermittent loose stools, fat intolerance, anorexia, headache and lassitude. These symptoms, with the exception of fat intolerance, should all gradually disappear roughly coincidental with the clearing of jaundice; persistence suggests continued activity of the hepatitis as discussed in the next section.

In a small group of cases the jaundice continues to increase rapidly or persists at high levels and the picture of acute liver failure develops. The patient becomes irrational and then comatose, and death usually ensues. Hemorrhagic phenomena are common. The actual case fatality rate was low, being 1.8 per thousand. In general, fatal cases fall into two groups, those that have an acute massive liver cell necrosis and die within four to ten days of onset and those that have a severe, persistent infection over a long period, up to two or three months. In the latter group there is usually some factor present which interferes with recovery, such as intercurrent infection or lack of adequate treatment. For example, a patient remains at work or on duty while jaundiced. Owing to the lack of rest and proper diet, he is unable to throw off the infection. Finally the liver damage becomes progressively worse until liver failure supervenes.

During the acute stage the liver is typically enlarged and tender. In patients that make a rapid recovery these findings disappear promptly, well in advance of the jaundice. In other cases only the tenderness decreases, the enlargement persisting for from one to many months. This has important prognostic significance, as will be shown later. It is important to remember that in a few cases no enlargement of the liver is apparent on physical examination at any time, especially when strict bed rest is enforced. This may be misleading, since the liver will almost invariably become enlarged if the patient is allowed to exercise.

Other physical findings are lymphadenopathy and splenomegaly as seen in the prodromal period. These tend to disappear within one to two weeks. Cases in which acute liver failure develop may or may not present a demonstrable progressive decrease in liver size.

Acute Stage Without Jaundice.—In a certain number of cases clinical jaundice fails to develop although in all other respects the clinical picture is the same. This form of the disease we have called acute hepatitis without jaundice. With proper management these cases run a shorter and milder course than those with jaundice. However, owing to obvious diagnostic difficulties the condition is often unrecognized, treatment is inadequate and either the liver lesion becomes more severe and jaundice develops or it persists without improvement for many months. Recognition is also important because of the obvious epidemiologic implications.

The frequency of this form of the disease in the Mediterranean theater is not accurately known, but judging from the evidence at hand it is probably at least as common as acute hepatitis with jaundice. It is of interest in this regard that studies of postvaccinal hepatitis made by two of us (M. H. B. and R. B. C.) at Fort Custer, Michigan, in 1942 showed that there were approximately two and one-half times as many cases without jaundice as with jaundice. Specifically there were 5,277 men at the post who had received yellow fever vaccine lot No. 368 in February 1942. Eleven per cent of these developed jaundice and were hospitalized. An additional 25 per cent developed, in the absence of icterus and after the same incubation period, symptoms and physical and laboratory findings identical in nature but milder in degree to those cases with jaundice. These data were obtained from examination of random samples, totaling 1,279 individuals, of the remaining nonhospitalized, supposedly well personnel.

Careful studies in approximately 100 cases of acute hepatitis without jaundice in the Mediterranean theater have shown clearly that this is a mild nonicteric form of acute infectious hepatitis. Chemical determinations of the serum bilirubin have not been abnormal in any of these particular cases but it cannot, of course, be stated that there was no disturbance of bile pigment metabolism at any time. In fact, it is probable that many cases presented such a disturbance but of such a mild and transient nature that it escaped detection. So, for practical purposes, they can be considered to be nonicteric.

The onset of this form of hepatitis is similar to that of acute hepatitis with jaundice. Enlargement of the liver usually appears after a week. Anorexia is present, but nausea and vomiting are not as evident as in the presence of jaundice. In the absence of an enlarged and tender liver the diagnosis is uncertain, but exercise will almost always make this finding evident.

Further proof of the identity of this form of hepatitis and of that with jaundice is offered by a comparison of the Hanger and sulfobromophthalein tests (chart 2). It will be noted that the curves are quite similar, abnormal tests being fewer in number and present for a shorter period of the disease in the nonicteric cases. Similar findings were obtained in the case of alkaline serum phosphatase and serum globulin.

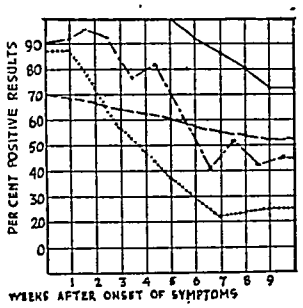

Chart 2.—Comparison of findings in acute hepatitis without jaundice (47 cases) with those in acute hepatitis with jaundice (171 cases) showing the percentage of positive results obtained each week. For the sulfobromophthalein test 3 per cent retention in one hour (5 mg. per kilogram) was taken as abnormal. Note the similarity of the curves. Solid line, sulfobromophthalein test in acute hepatitis with jaundice; broken line, sulfobromophthalein test in acute hepatitis without jaundice; line of dashes and dots, Hanger test in acute hepatitis with jaundice; dotted line, Hanger test in acute hepatitis without jaundice. Note that no sulfobromophthalein tests were done in the presence of clinical jaundice.

Convalescent Stage.—It was first noted in 1942 during our study of postvaccinal hepatitis that, although patients might appear to be recovered and nonicteric while at bed rest, when allowed to be ambulatory and especially when allowed to exercise they would not infrequently develop a recurrence of symptoms, physical findings and occasionally even jaundice. This obviously is a matter of great importance, especially in the Army, where a man discharged from the hospital must be prepared to return at once to the rigors of combat duty. Consequently the effect of exercise both on the patient and on the disease has received most careful study. Over 450 "exercise tolerance tests" have been run in various stages and types of hepatitis and the results studied from both the clinical and the laboratory point of view. Briefly, it has been found that, as long as activity of the hepatitis is present, exercise will increase the physical findings, the symptoms and the laboratory evidence of liver dysfunction. For practical purposes the development of a large and tender liver has been taken as evidence of an abnormal test. The actual effect of exercise in the individual case depends, on the one hand, on the degree of activity of the hepatitis and, on the other hand, on the severity and duration of the exercise. Exercise induced findings characteristically persist for from a few days to many weeks and constitute a true relapse of the disease. In some cases jaundice may recur, and the relapse may run a much more severe and prolonged course than the primary attack (chart 3). When the hepatitis is less active or when the exercise taken is milder, either the disease may reach a steady state and neither improve nor progress, or gradual recovery may occur. Recovery is delayed by exercise and promoted by rest.

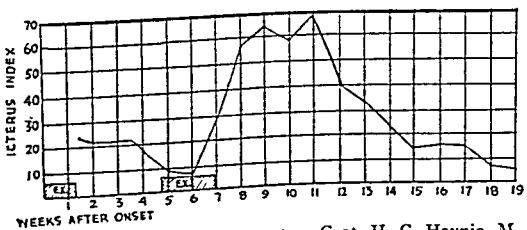

Chart 3 (C. M., aged 20 years, courtesy Capt. H. C. Haynie, M. C.).—Acute hepatitis with jaundice, showing icteric relapse caused by exercise. This patient was allowed to work in the ward from the fifth to the seventh week. Although nonicteric, active hepatitis was obviously still present. Note the severity and duration of the relapse compared to the primary attack.

Thus the effect of exercise must be considered in the evaluation of clinical recovery. Or, in other words, the absence of jaundice, symptoms and abnormal physical findings while the patient is at bed rest cannot be accepted as final evidence of clinical recovery; only when these abnormal findings remain absent after exercise can the physician be certain. This reaction is essentially analogous to the febrile response to exercise of the patient with tuberculosis or to hematuria in convalescent acute glomerular nephritis. Because of these special features, the convalescent period has been set aside for discussion as a separate stage of the disease.

In the Mediterranean theater the average case of acute hepatitis with jaundice requires from six to eight weeks of hospitalization (chart 4). This includes three to five weeks of bed rest followed by seven to ten days on an ambulatory status and finally seven to ten days of exercise. For civilian practice this program could be modified by substituting work for the exercise. Whether the other periods could be shortened is a matter of clinical judgment.

Employing a graduated exercise tolerance test as a final criterion of clinical recovery, it is found that in many cases of hepatitis recovery has not occurred even after three months of hospitalization. This group represents approximately 10 per cent of cases. It is probable that they have been largely overlooked in the past.

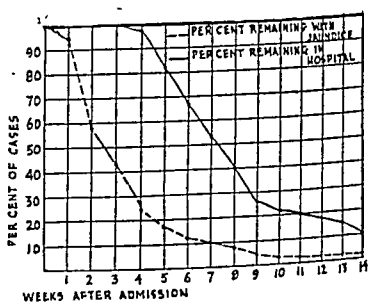

Chart 4.—Duration of elevated icterus index (acetone) and of total hospitalization in an unselected group of 78 cases of acute hepatitis with jaundice. The onset of jaundice was within three days of admission in 84 per cent. Broken line, per cent remaining with jaundice. Solid line, per cent remaining in the hospital.

LABORATORY FINDINGS

Prodromal Stage.—The laboratory findings at onset are variable, especially in those cases with a prolonged prodromal period. At present no really diagnostic tests are available, although several tests allow of a presumptive diagnosis.

A mild leukopenia is usually present associated with 5 to 20 per cent of atypical lymphocytes similar to those of infectious mononucleosis.[8] Occasionally these cells may reach 60 per cent of the total leukocytes. This is one of the earliest and most constant findings. Heterophile antibodies have always been absent on repeated examinations. The erythrocyte sedimentation rate is normal or moderately elevated.

Serum bilirubin as measured by the quantitative van den Bergh, acetone icterus index[3] or ordinary icterus index is usually normal unless jaundice is imminent. How frequently the qualitative van den Bergh shows a prompt direct reaction under such circumstances is not known, but there is suggestive evidence that it may be a significant and early finding. Bilirubinuria as indicated by the methylene blue test may or may not be present but usually appears one to three days prior to jaundice. Urobilinogen determinations have not been of value in our hands both because of variable results and because other acute febrile conditions may produce a positive test. However, we have

8. Minot, G. R., and Jones, C. M.: Infectious Jaundice, Boston M. & S. J. 189: 531 (Oct. 18) 1923.

had only a limited experience with Watson's newest method.[9]

Certain special tests have been found valuable, especially the cephalin cholesterol flocculation of Hanger. This is positive in 50 to 75 per cent of cases at this stage. The sulfobromophthalein dye retention and the alkaline phosphatase are also frequently abnormal.

Acute Icteric Stage.—The duration of elevated icterus is shown in chart 4. The only other determination of practical value at this stage is the prothrombin time.[10] A poor prognosis is indicated by an increase in the prothrombin time especially if there is no response to vitamin K therapy. The sedimentation rate is usually normal in the presence of jaundice.

Many other interesting laboratory observations have been made. The Hanger test and serum alkaline phosphatase are abnormal in over 90 per cent of cases during the first few weeks of the disease. The sulfobromophthalein test was positive in all cases tested during the first five weeks (chart 2). The serum globulin[11] was elevated over 2.5 Gm. per hundred cubic centimeters in more than 60 per cent of cases during the first two weeks, while the serum albumin was below 4.0 Gm. per hundred cubic centimeters in only 30 per cent. The serum amylase[12] tended to be low (below 60 units, Somogyi) during the first two weeks of illness and abnormally high (over 180 units) in the third and fourth weeks. The colloidal gold test[13] was usually positive during jaundice. Urobilinogen was often absent from the urine for a few days during the period of rising icterus and then appeared in abnormal amounts.

Acute Hepatitis Without Jaundice.—In the absence of jaundice, laboratory findings assume increased importance. In our cases of this type there was no laboratory evidence of increased bilirubin in the blood or urine during the period of observation, although such evidence may have been present prior to hospitalization.

The sulfobromophthalein dye retention is abnormal (over 2 per cent in one hour) in 94 per cent of cases and constitutes our most reliable test (chart 2). The Hanger test is positive in 53 per cent of cases, but many were not tested during the early stage of the disease, when the test is most likely to be positive. The alkaline phosphatase, serum globulin and amylase all are abnormal in a somewhat smaller percentage of cases than in acute hepatitis with jaundice.

Convalescent Stage.—The laboratory findings that have clinical significance during convalescence are relatively few. They are the serum bilirubin, the qualitative van den Bergh and the sulfobromophthalein dye retention. A serum bilirubin as determined by the quantitative van den Bergh of over 2.0 mg. or an icterus index of over 20 or a prompt direct qualitative van den Bergh especially in the presence of a total serum bilirubin of over 1.0 mg. is usually indicative of active hepatitis. Similarly a sulfobromophthalein dye retention of more than 10 per cent in one hour or about 16 per cent in forty-five minutes is almost always associated with activity. Values in the range of 6 to 9 per cent in one hour or 8 to 16 per cent in forty-five minutes are very suggestive of activity.

Positive Hanger tests, alkaline phosphatase values over 4.0 units and elevated sedimentation rates are not necessarily indicative of activity in this stage of the disease.

The oral hippuric acid liver function test[14] in our hands has shown practically no correlation with the clinical condition of the patient. Thus the test frequently gave relatively normal results during the acute stage and very low results in the convalescent period. Furthermore, the oral administration of aminoacetic acid in the form of gelatin just prior to the test resulted in a normal hippuric acid excretion in 153 out of 156 cases. Dietary factors were probably too prominent to permit use of this test as a measure of liver function.

DIAGNOSIS

The problems of diagnosis are quite different with each stage of the disease and must be treated accordingly.

Prodromal or Preicteric Stage.—This picture simulates that of any acute febrile illness, and diagnosis except during an epidemic is at best tentative. It is usually necessary to await the appearance of an enlarged tender liver or of jaundice before the diagnosis can be established. Upper respiratory infections, atypical pneumonia, acute enteritis or dysentery, influenza and malaria are the most common differential conditions.

In early cases without hepatomegaly suspicion should be aroused by percussion tenderness over the liver and by tenderness in the right costovertebral angle. This finding, associated with low cervical adenopathy, characteristic symptoms and the presence of other cases in the neighborhood should lead to further investigation. The blood picture is usually helpful. The presence of bilirubinuria, bilirubinemia or splenomegaly is, of course, very suggestive. A positive Hanger test or a strong sulfobromophthalein dye retention also provides valuable evidence.

It must be remembered in employing these or other tests that there are nonspecific toxic liver changes in many febrile states with associated transient liver dysfunction, so that there is at present no test which is specific for infectious hepatitis. Further, we have discussed only those laboratory procedures with which we have had experience and do not wish to imply that better tests may not be available.

If there is reasonable suspicion of infectious hepatitis and other conditions have been excluded as far as possible, it is necessary to wait until jaundice or hepatomegaly develops before being certain of the diagnosis. In the event that these signs fail to appear it is necessary to get the patient up and allow him to exercise. When this is done within two weeks of onset, one is safe in assuming that the liver will become enlarged and tender if infectious hepatitis has been present.

Acute Icteric Stage.—The diagnosis in the presence of jaundice resolves itself into a discussion of the causes of icterus which need not be taken up here. In regard to the simulated picture of an acute condition of the abdomen it is important to remember that the liver is probably always enlarged and tender.

Acute Hepatitis Without Jaundice.—This diagnosis can be made in the presence of an enlarged and tender liver which persists for four or five days or more

and is associated with the symptoms previously described. If there is doubt regarding the liver findings, the exercise tolerance test should be employed.

Laboratory evidence of liver dysfunction is more reliable here than in the prodromal period because fever is usually absent during most of the acute stage. In addition to the clinical findings, either a positive sulfobromophthalein or a positive Hanger test should be obtained. Laboratory tests alone cannot be relied on to make the diagnosis, since a number of other conditions, notably malaria and atypical pneumonia, can be associated with similar laboratory findings.

MANAGEMENT

The cardinal principles in the management of acute infectious hepatitis are early and adequate rest and proper diet. We have very strong evidence that early and reasonably complete bed rest for an adequate period will decrease the severity and shorten the duration of the disease and decrease the percentage of cases with delayed convalescence. We have also found that a high protein (200 Gm.), low fat (40 Gm.) and high carbohydrate (400 Gm.) diet has a similar effect. On the basis of experimental evidence [15] it appears probable that the high protein constituent of this diet, especially beef, milk and cheese, is the most important therapeutic factor. The importance of a low fat intake is still in dispute. Carbohydrates should be present in large amounts. There is no evidence that excessive amounts of vitamins are desirable; on the contrary, too much vitamin B_1 may be harmful.[15] One to 3 mg. daily by mouth is adequate. Alcohol is contraindicated during all stages of active hepatitis.

In the prodromal stage the first consideration is to establish the diagnosis and to put the patient to bed with the aforementioned diet. Treatment is otherwise symptomatic. It is desirable to examine the urine and blood repeatedly for evidence of approaching jaundice.

Treatment in the acute stage with jaundice may be complicated by nausea and vomiting. This is best controlled by maintaining a fluid intake of 3,000 cc. daily. If adequate fluids cannot be tolerated orally, they should be given by vein. Ten per cent glucose in water is probably the best form, or 5 per cent glucose in saline if vomiting is troublesome. In severe cases, especially when the protein intake is low, intravenous plasma or whole blood is desirable. Two plasma units a day provides adequate and suitable protective protein. If hemorrhagic phenomena occur or if the plasma prothrombin level is low, vitamin K should be administered parenterally in doses of 2 to 4 mg. Whole blood transfusions are the most reliable method of counteracting hemorrhage of serious nature.

For abdominal cramps or pain, belladonna or atropine should be used. Morphine is to be avoided, as these patients overreact to the usual doses. This is also true to a lesser extent of the barbiturates. Bile salts are contraindicated because of possible toxic effects on a damaged liver.

In the convalescent stage, management is most important. The following criteria have been successfully employed in the Mediterranean theater to determine when the patient can be allowed out of bed:

1. At least three weeks of bed rest.

2. Liver normal size on physical examination or, if slightly enlarged, it must be definitely nontender.

3. Absence of symptoms, especially lassitude and anorexia.

4. Normal level of serum bilirubin for one week or, if slightly elevated (under 2.0 mg. per hundred cubic centimeters or icterus index under 16) absence of a prompt direct qualitative van den Bergh reaction.

5. Other laboratory tests. It is desirable to have the sulfobromophthalein dye retention under 10 per cent in one hour, and best to have it under 6 per cent. It is preferable but not necessary to have a normal Hanger test and normal alkaline serum phosphatase.

If only one of these criteria has not been met it is best to allow one more week in bed before getting the patient up. If while ambulatory the liver becomes definitely larger and tender, or if already enlarged it becomes more tender, further bed rest is indicated. When findings are questionable it is safe to proceed with the ambulatory regimen until they become either positive or negative. In civilian practice if patients are allowed to return to work after being out of bed for seven to ten days they should be reexamined after ten to fourteen days to make sure that the liver is not enlarged and tender.

PROGNOSIS

The immediate prognosis in infectious hepatitis is in general excellent. However, since therapeutic measures become progressively less effective as acute liver failure develops, it is important to recognize early those features which suggest a serious course. The disease is liable to be more severe in the presence of a past history of infectious hepatitis within several years, exposure to carbon tetrachloride or other liver poisons, chronic alcoholism or in persons over 40 years of age.

Caution should be employed and treatment intensified in cases in which the bilirubinemia continues to increase or persists at high levels for ten days or more and is associated with nausea and vomiting. Persistence in spite of adequate treatment of moderate levels of serum bilirubin (5 to 10 mg. per hundred cubic centimeters) associated with severe anorexia and nausea for three weeks or more has a similar significance. A serious prognosis is not warranted unless the patient becomes disoriented or irrational. Recovery may occur even after coma has developed. Hemorrhagic phenomena and a decidedly prolonged prothrombin time that fails to respond to vitamin K is a serious sign.

The prognosis as to duration of illness and the development of chronic hepatitis or relapse is difficult to predict. In general, patients that have a severe acute attack, a very high serum bilirubin (15 mg. per hundred cubic centimeters or more) or show any of the features that are significant in the immediate prognosis are more likely to have a prolonged illness. A relapse is consistently associated with a prolonged course (chart 3). Data regarding the final outcome will be presented in a subsequent paper.

COMMENT

Certain relatively new features of infectious hepatitis have been presented. One of the more important is the deleterious effect of exercise and the beneficial effect of rest. Both reactions are of great diagnostic importance as well as having obvious therapeutic implications. Owing to the longer duration of this disease than peviously recognized and the persistence of activity of the hepatitis after disappearance of icterus, the value of the exercise effect in estimating the degree of recovery has also become apparent. Thus this whole relationship is perhaps the most constant feature of infectious hepatitis in all stages.

15. György, P.: Experimental Hepatic Injury, Am. J. Clin. Path. 14: 67 (Feb.) 1944. Himsworth, H. P., and Glynn, L. E.: Toxipathic and Trophopathic Hepatitis, Lancet 1: 457 (April 8) 1944.

Data substantiating the therapeutic effectiveness of dietary measures cannot be presented here. However, the results are convincing, although as yet we cannot be certain which factor, the high protein, low fat or better caloric intake is the most important. There is ample experimental evidence that the first factor is quite important.

Early treatment is certainly desirable, yet care must be taken not to make the diagnosis of infectious hepatitis indiscriminately else many patients with transient illnesses may be unnecessarily invalided. Regarding the criteria for recovery, it should be remembered that even though patients are permitted to be up and permitted to return to work before these criteria are met, most will go on to recovery. However, recovery will require much longer and during this time partial disability and inefficiency will be present as well as an increased risk of relapse or chronicity.

It cannot be definitely stated whether this disease is identical with so-called catarrhal jaundice as seen in civilian practice. However, from a clinical point of view it seems to be very similar. Although it would appear to be a more serious condition in the army overseas than among civilians in the United States, this is probably only in part due to circumstances incident to combat but is also the result of a failure to recognize the duration of the disease and the clinical picture associated with the sequelae by civilian physicians.

SUMMARY

1. The course of acute infectious hepatitis is usually characterized by an acute febrile nonicteric prodromal stage of one to two weeks' duration followed by the acute icteric stage. The convalescent stage is treated separately because of certain special features.

2. The condition of acute hepatitis without jaundice is a milder form of the icteric disease. This type of hepatitis, which is probably as common as that with jaundice, is important because inadequate treatment may result in the development of chronic hepatitis and also because of the epidemiologic implications.

3. The fundamental effect of exercise in producing relapse has led to the use of an exercise tolerance test for purposes of diagnosis and for the determination of recovery. If active hepatitis is present in any stage of the disease, exercise will result in an enlarged and tender liver which persists for several days or weeks.

4. Early and reasonably strict bed rest of adequate duration and a high protein diet are the fundamental therapeutic measures and will result in shortening the course of the disease and decreasing the incidence of chronic hepatitis. The disappearance of jaundice is not necessarily an indication of recovery.

5. The average case of infectious hepatitis requires from six to eight weeks for recovery. From 5 to 10 per cent are still not clinically well at the end of three months.

Most Distinguished Arab Physician.—Perhaps the most distinguished Arab physician who subscribed to the pneumatic and the anima oculi theories of Galen was Avicenna (Abu Ali al Husain ibn Sina, 980-1037 A. D.). His medical work "The Cannon" (Qanun) served as a textbook longer than almost any other book in the history of medicine. It was used as late as 1650 in the universities of Montpellier and Louvain.—Gordon, Benjamin Lee: The Romance of Medicine, Philadelphia, F. A. Davis Company, 1944.

CERTAIN DEFECTS OF A NATIONWIDE PLAN FOR PROVISION OF ADEQUATE MEDICAL CARE

W. G. SMILLIE, M.D.
Professor of Public Health and Preventive Medicine, Cornell University Medical College
NEW YORK

A nationwide plan for provision of medical care is embodied in the Wagner-Murray Bill S. 1050, which has been presented to Congress for consideration. The American Public Health Association has formulated a policy, "A National Program for Medical Care," [1] and the Committee of 29 on Research in Medical Economics presented the "Principles of a Nationwide Health Program" [2] in December 1944. These plans are of such great personal interest to every individual and family in the nation that they deserve most careful thought.

These plans have been under active consideration by sociologists, economists, labor organizations, public health workers and the medical profession for several years. The discussions have in many instances been acrimonious and often injudicious. For the most part the discussions have been conducted by groups who may be under suspicion of having a certain amount of bias. The majority of contributors have been the public health officials who would probably be the group to administer the plans; the sociologists, professional and amateurs, who are presumed to know just what is wrong with our social system and have a precise remedy for its correction; and the representatives of organized medicine, who are directly concerned because physicians are the key personnel in any plan for provision of medical care.

Very little attention has been given, as yet, to the opinion of those who are to be the recipients of this service. A few public opinion polls have been taken, but the analyses of the results have been ambiguous. "Wouldn't you like to have better and cheaper medical care than you are receiving at present?" "Why are you mad at doctors?" "Don't you think hospital charges are exorbitant?" "Would you rather choose your own doctor or would you be willing to accept any physician that might be available?" Public opinion polls of this general tenor have not been very enlightening.

The three plans for nationwide medical care that have been mentioned have the great merit that they present a positive, definite, detailed outline of administrative procedures that are committed to a clearcut course of action. They all prescribe a system of nationwide, compulsory, contributory medical insurance which will be collected and administered by the federal government. The plans are the result of a great deal of careful thought and preparation by very capable men who have devoted their lives to a consideration of health promotion of the people and who understand the components of adequate medical care.

These men would be the first to admit that all the plans for a nationwide compulsory, contributory system for provision of medical care have certain inherent defects which should be thoroughly discussed and fully

1. Preliminary Report on a National Program for Medical Care, Am. J. Pub. Health 34: 984, 1944.
2. Principles of a Nationwide Health Program, Report of the Health Program Conference of the Committee on Research in Medical Economics, New York, 1944.

understood before they are accepted by the people that they are intended to benefit.

The bitter remembrance of the last great national fiasco in hasty social reform, which was initiated largely because the people did not understand the full implication and significance of the national prohibition act, is still too keenly felt to warrant ill considered action in other matters of nationwide social policy.

If these plans have any defects, let us consider them. We may then determine whether or not the benefits that they will provide will greatly outweigh the sacrifices that they will entail.

INFRINGEMENT ON LOCAL SELF GOVERNMENT

Many thoughtful people are of the opinion that a nationwide plan for provision of medical care has a fundamental defect in that it represents an encroachment on local self government, and, unless proper safeguards are taken, that it will undermine the very foundation stones on which our nation was built. All people instinctively desire security and long for the very best social conditions that can be obtained for themselves and for their families. But most of us are unwilling to possess these benefits at the cost of personal freedom.

The issue is a simple and straightforward one. May I present it, not from the point of view of the practicing physician or the public health administrator, but from the point of view of a recipient of these services. As far as I can interpret the thinking of the average American, I encounter the following trend of thought:

How much individual freedom am I willing to sacrifice in order to obtain security? And in sacrificing that freedom am I sure that I shall reap the full benefits of individual and community security?

Is it not true that the ideas of security at any cost have been imposed on us by those who have come from, or borrowed their ideas and social philosophy from, those European nations which have preferred security to freedom? Our traditions have been to permit as much freedom to the individual as is possible, as far as the exercise of this freedom does not interfere with the rights of others and does not produce a community hazard or jeopardize the security of all. There is a real danger, of course, that in our demand for individual freedom we may foolhardily sacrifice all opportunity for individual, family and community security.

On the other hand, if we demand security at any cost, then it is obvious to most of us that we shall pay too high a price for it. Our democratic traditions have required the maintenance of the principle of local autonomy in community government. We have all understood the quite obvious and very important advantages that would accrue under a system of government by benevolent centralized authorization.

But a benevolent, paternalistic, all powerful, gracious, all wise and generous centralized government is our conception of God in his Heaven. This idealistic Paradise is supposed to be reserved to us for a life to come. As long as we remain on earth and must follow natural laws, we feel very deeply and instinctively that the individual rights of personal choice, together with local autonomy in determination of communitywide governmental and social policies, is a basic individual and community right.

It is much more than a matter of financing, organization or administration. In such simple matters as provision for medical care the principle lies much deeper than a desire to have a physician of one's own choosing or to select some one hospital or some method of therapy that appeals to our individual sense of the appropriate. We may believe, for example, that Christian science is not an effective therapeutic procedure, but we shall defend the right of a man to choose these procedures if he so desires and as far as this choice does not represent an infringement on community security.

As Havens[3] has pointed out, social security, and economic security as well, is a state of mind. No centralized government, no institution, no individual should assume the authority, nor should they be allowed the power to provide security for the individual if such security is offered at the expense of personal freedom. Such a security should be refused and spurned with scorn. This is the security of the Israelites in the land of Egypt, or the security given the Negro on his master's plantation in the South.

The aged, the helpless and the infirm should be given security by the community as a matter of course. But the young, virile, aggressive, ambitious, inventive individual, community or state does not ask for or desire a nationwide, comprehensive, beneficent, compulsory, paternalistic system of social and economic security that is planned by a few men—no matter how wise, how socially minded or how public spirited they may be.

The average man feels instinctively that systems of social security should grow slowly, from below upward, developing out of the social conscience of the mass, rather than be imposed from above downward. There lies deep in the heart of every man a profound and wholesome distrust of the pontifical, perfectly well meaning, self-assumed certainty of omnipotence with which these plans are presented. This innate feeling of distrust is the result of a certainty that no individual or group of individuals has the knowledge to formulate or the talent to administer a completely comprehensive plan for provision for medical care for the whole nation of over 130 million people, on a compulsory, contributory basis, no matter how well grounded they may be in social theory. How can such a plan be flexible enough to meet the fundamental requirements of every community and the needs of each individual and still retain the principles of personal freedom and the maintenance of the democratic principles that are the very basis for the American mode of life?

THE UNITED STATES IS A DIVERSE NATION

One of the major difficulties with a uniform, centrally administered nationwide plan for medical care of all the people is that we are not a homogeneous, but a diverse, people. The United States consists of forty-eight widely different and quite independent governmental units. They vary enormously in area, population, economic status, type of industry, traditions and culture. A medical plan that would be suitable for one section of the country would be quite unsuited to another. This is an additional reason why no nationwide plan could be devised which would be flexible enough to suit all situations equally well.

LIMITATIONS OF FEDERAL FUNCTIONS

As long as our Constitution stands, each state is a sovereign power, and the federal government possesses only those governmental functions that are expressly

3. Havens, R. D.: The Burden of Incertitude, Rochester, N. Y., University of Rochester Press, 1944.

granted to it by the states. Many states are quite unwilling to sacrifice the principle of local self government in relation to provision of medical facilities for all for the obvious advantages of a centrally administered, compulsory, nationwide plan.

Each type of governmental authority—federal, state or local—has certain functions which it is best fitted to administer. For example, the federal government is obviously best fitted to administer public health matters that are of international significance or of interstate concern. But other governmental services are supplied best by the local community. Let us take a very simple example: The local community in which I reside supplies my family with an adequate and excellent supply of water. It is true that the local water supply system is under the supervision of the division of sanitary engineering of the state board of health, and the quality of the water conforms to the national standard for interstate carriers, but the administration of the service is a local responsibility. If the state board of health should attempt to administer our local water supply system, it would be both costly and inefficient. If the federal government was to assume responsibility for administration of the water supply service of our town, I am perfectly certain that my family would be thirsty a good part of the time.

THE PURSE DETERMINES THE POLICY

Each of the plans presented to us provides for a certain component of local autonomy in administration. But each plan also provides that the collection of funds, and therefore disbursement of funds as well, shall be a primary function of the federal government. Now it is an axiom of any administrative unit—be it family, small business firm, corporation or community—that "the purse determines the policy." Thus any autonomy that might be granted by the federal health agency to a local community would be the autonomy of a child who receives his allowance from his father each Saturday, on the basis of a week's good behavior.

COMPARISON OF COMPULSORY, CONTRIBUTORY MEDICAL CARE WITH COMPULSORY EDUCATION

Dr. Alan Gregg, a member of the Committee of *29*, has drawn the analogy between a compulsory, contributory plan of medical care and communitywide provision for compulsory education which we have all accepted as a basic ingredient of community life. This analogy is an excellent one, and we are quite willing to accept it.

But it must be remembered that our compulsory educational system was not imposed on us from above by the federal government, on a nationwide basis.

The great secret of success of our educational system is that it is an outgrowth of the conscious desires of the great mass of the people. It emerged slowly, through many years of trial. Always it has maintained the basic feature of local autonomy and local community determination of policy. State standards have been of great value in the improvement of the system. State subsidies to less favored communities are an essential part of the plan. The federal government has been of assistance in promotion of nationwide standards of education. But the principle of local community responsibility for schools is the very keystone of the plan, whereas a federally sponsored and administered plan would be certain to fail.

LOCAL AUTONOMY IS ESSENTIAL IN ANY SYSTEM FOR COMPREHENSIVE MEDICAL SERVICE

The majority of the people who have given this question due consideration believe that the most satisfactory system for development of adequate medical services for the United States as a whole is the much less comprehensive, but much sounder, system of slow evolutional development, on a local community basis, of statewide programs that are framed to meet the needs of each local and state situation. Minimum standards of adequacy of medical care may be provided by the federal government, and federal government subsidy may be provided as grants-in-aid to states, during the developmental stages of these plans. Formulation of nationwide standards and administration of federal subsidies are the function of the United States Public Health Service, the Children's Bureau or, better still, a separate National Department of Public Health with a cabinet member at its head.

This system was used with success in the gradual development of full time local health departments under the Social Security Act and was successful in meeting each particular need in each area in the country.

A STATEWIDE MASTER PLAN

A comprehensive master plan might be formulated by each state, so drawn as to meet its own requirements. The advice of the United States Public Health Service and other federal agencies should be sought in drawing up these plans. But the basis of each plan should be that primary responsibility for administration of the program must rest with the local community. It would be anticipated, of course, that each local community would develop its plan under state guidance.

Not only determination of policy, but the financing of each plan, should be a local responsibility. Supplementary aid may be furnished by the state where the particular situation requires such assistance.

It must be admitted that the evolution of plans for improvement in medical services on a local autonomy basis is discouragingly slow. It does not keep pace with advances in medical science or with improvements in technic of administration. But it must be remembered that the evolution of social structure under the principles of democratic government is a slow, tedious, discouraging, painful process. Yet somehow, despite all its faults, we like it.

This, in my opinion, is an interpretation of the *feeling* of the average thoughtful American in relation to provision of adequate medical care for the family and the community.

He is quite willing to promote any plan which will be of real benefit to the health and welfare of his family and his community but is quite unwilling to accept a revolutionary, nationwide program of social betterment that has not gone through the fire of long, extensive, careful test under a great variety of conditions.

Most important of all, he is unwilling to surrender the principle of local community autonomy and to delegate authority to the federal government for the control and administration of such a personal and intimate matter as medical care of himself and his family.

1300 York Avenue.

FRACTURE OF THE SHAFT OF THE FEMUR IN ADULTS

EVALUATION OF METHODS OF TREATMENT

COLONEL FRANCIS M. McKEEVER
Chief of Surgical Service and Chief of Orthopedic Section, Percy Jones General and Convalescent Hospital, Battle Creek, Mich.
MEDICAL CORPS, ARMY OF THE UNITED STATES

Fracture of the shaft of the femur is the cause of prolonged total disability and all too frequently of a severe permanent disability. Because of the long period of total disability and the severe economic burden imposed by this injury there have been constant efforts to develop methods of treatment which will shorten enforced recumbency and thus lighten the financial strain of this injury. The objectives of these technics have been to effect recovery in the shortest possible time and at minimal cost.

My purpose in this paper is not to criticize any technic or procedure as that technic is practiced by its originators or employed by those highly skilled in its use but rather to show the results which accrue from the promiscuous use of procedures which require high skill and special armamentarium in the hands of an average group of surgeons. The stanchest champion of internal fixation of fractures of long bones in this country has clearly, emphatically and consistently warned against the general use of this method by those unskilled in its application or restricted as to facilities for its employment.[1]

This study is based on the observation of 47 patients treated in many different army hospitals by many different surgeons. I did not initiate the treatment of any, but all patients were cared for ultimately by me. They all had closed fractures of the shaft of the femur. None had compound fractures. The patients were all men between the ages of 18 and 40 who were in excellent physical condition and in whom the healing process would be expected to be optimum. Excellent hospital facilities, prompt attention and splendid general care were available for all.

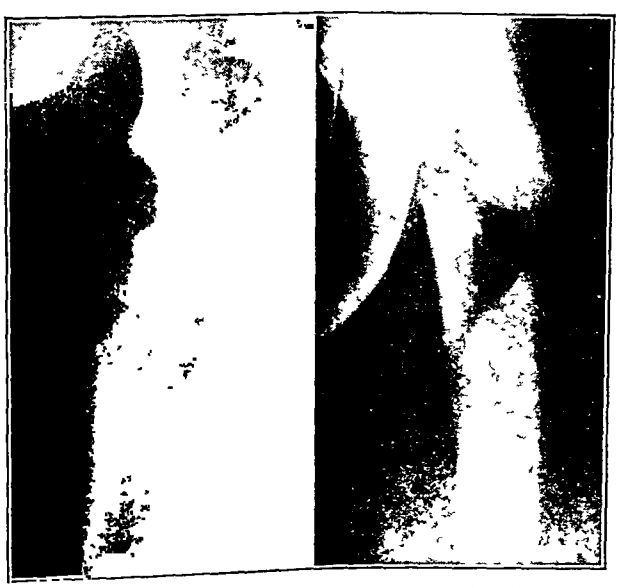

Fig. 1.—Appearance of fracture of upper third of shaft of femur three months after injury. Poor position of fragments, good alinement, callus

Twenty-three patients were treated by some form of suspension traction, usually skeletal traction applied with a Kirchner wire, but in a few patients by a larger pin of the Steinmann type.

Fig. 2.—Six months after injury, bony union

Seventeen patients were subjected to open reduction and internal fixation with plate and screws. In the group of 17 patients treated by open reduction and plating this treatment was elected by the surgeon for 10 patients. In 7 patients it was resorted to only after a trial of more conservative measures, in the surgeon's opinion, had failed to result in satisfactory position of the fragments.

It is to be remarked here that absolute end to end apposition of the fractured fragments is not a necessary requisite for a good result or even for bony union of a fracture. While an anatomic reduction should be striven for, the failure of any method to attain a perfect x-ray reduction does not justify a change to a more radical procedure, provided there is good alinement, negligible shortening and reasonable contact of the fragments. The only condition which makes open reduction positively indicated is the certainty or well founded suspicion that soft tissue is interposed between the fragments (figs. 1, 2 and 3).

Seven patients were treated by means of external skeletal fixation, with use of one of the many mechanical devices for this type of treatment.

The average period of time elapsing between the injury and the date of evaluation was twelve months. The shortest period of follow-up was six and one-half months. The longest period of follow-up was twenty-four months. In all instances in which the period of follow-up was less than one year this was due to the fact that recovery had been adequate for the patients to be discharged from medical supervision and returned to their duties.

1. Murray, C. R.: Primary Operative Fixation in Fractures of the Long Bones in Adults, Am. J. Surg. 51:739-747 (March) 1941; The Status of Fracture Treatment in the Field of Surgery, Surg., Gynec. & Obst. 62:433-434 (Feb., no. 2A) 1936

To determine the efficiency of these three types of treatment, the following factors in each method were examined and compared:

1. The period of absolute recumbency of the patient
2. The total necessary period of protection of the fracture.
3. The time required for roentgen evidence of bony union.
4. The status of the joints of the extremity.
5. The degree of shortening of the leg
6. The degree of muscular atrophy of the thigh
7. The complications arising from each method of treatment
8. The secondary operative procedures which resulted from complications in each type of treatment

The results obtained in the following groups of patients are the product of what may be considered a median cross section of the surgical talent of the nation. It is felt, therefore, that these results may be considered representative of the results to be expected in the hands of the average surgeon. They are claimed to be neither better nor worse.

PERIOD OF ABSOLUTE RECUMBENCY

By the period of absolute recumbency is meant the time each patient was confined to bed. In this time are included all days of bed recumbency made necessary by complications arising directly from the method of treatment. This is a figure of importance from the economic point of view as during this period the patient needs at least nursing care. For the patient in traction it necessitates hospitalization. For the patient in a cast nursing care at home might suffice.

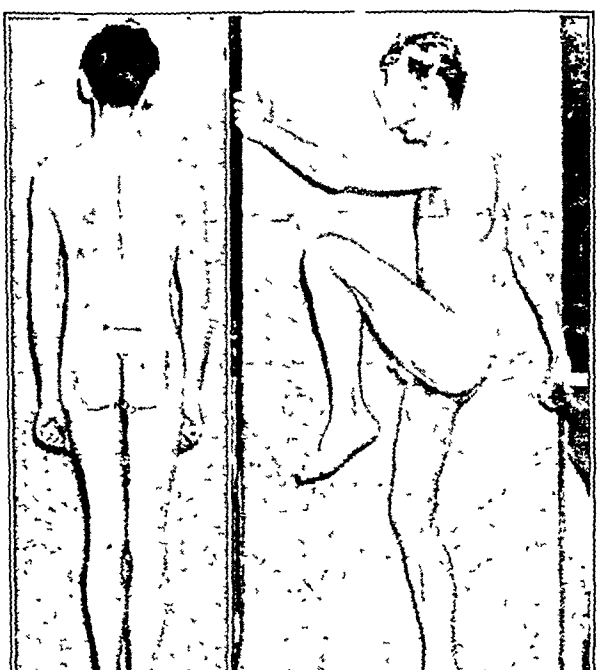

Fig. 3.—Patient whose roentgenograms are shown in figures 1 and 2 seven months after injury. *A*, no shortening, no pelvic tilt or scoliosis, *B*, good motion in joints

The shortest period of total recumbency occurred in a patient treated by external skeletal fixation. This was seventy days, as compared to seventy-seven days for internal fixation and ninety days for traction. However, the seventy day period was far from the rule and was the interval of recumbency in only 1 case. The longest period of recumbency, 365 days, occurred in a patient treated by internal fixation and was closely followed in a patient treated by external skeletal fixation who was in bed 326 days. Each of these prolonged periods of bed recumbency was made necessary by

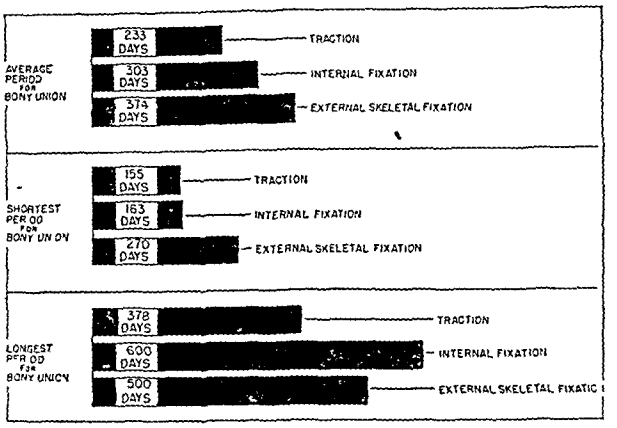

Fig. 4.—Time required for x-ray evidence of bony union.

complications arising directly from the type of treatment. The patient whose femur was plated developed a pseudarthrosis which necessitated a bone graft. The patient treated by external skeletal fixation had a delayed union and osteomyelitis about multiple pin holes, which required a squestrectomy. The longest period of time any patient treated by traction was confined to bed was 193 days, a total invalidism significantly shorter than by either of the other methods.

The average period of recumbency for patients treated by internal fixation was 185 days, by external skeletal fixation 168 days and by traction 145 days. The enforced recumbency in the group treated by traction and by internal fixation needs no explanation. It is the time during which the patient was suspended in a splint or was confined in a cast. The period of bed

TABLE 1.—*Period of Absolute Recumbency*

Length of Period	Traction (42 Patients)	Internal Fixation (Plate) (17 Patients)	External Skeletal Fixation (7 Patients)
Average period	145 days	185 days	168 days
Shortest period	90 days	77 days	70 days
Longest period	193 days	365 days	326 days

recumbency in patients treated by a method designed to produce early ambulation, that is, external skeletal fixation, needs clarification. This unduly long period was due to the fact that 5 of the 7 patients treated in this manner required supplementary treatment either by a cast or by traction. Removal of the pins and apparatus in over half the cases was necessitated because of infection about the pin sites, before the fracture was solid enough to permit ambulation in a brace, without danger of angulation. A small part of this long period of recumbency in patients treated by external skeletal fixation may be attributed to inexperience in the method and to a lack of the courage to have the individual on his feet, on the part of the surgeon.

TOTAL NECESSARY PERIOD OF PROTECTION

The total necessary period of protection is the number of days which intervened between the injury and the time the patient was able to bear full weight without

brace or crutches. All this time the patient is of little or no economic value and is never entirely independent in his activities because weight cannot be unguardedly borne on the extremity.

TABLE 2.—*Total Period of Protection*

Length of Period	Traction (23 Patients)	Internal Fixation (Plate) (17 Patients)	External Skeletal Fixation (7 Patients)
Average period	219 days	266 days	370 days
Shortest period	144 days	150 days	251 days
Longest period	367 days	637 days	665 days

The shortest individual total period of protection was in a patient treated by traction. This period was 144 days. In the group treated by internal fixation the shortest period of total protection was only slightly longer, 150 days. The shortest time in the group treated by external skeletal fixation was 251 days, a great increase of partial disability. The longest single period of total protection also occurred in this group and was 665 days. In the group treated by internal fixation 1 patient was not bearing weight unprotected until 637 days after injury. This was again the result of a complication which necessitated a bone graft. Of all patients treated by traction the longest any individual required protection was 367 days, a period almost ten months less than by the other forms of treatment.

The average period of total protection in the group treated by traction was 219 days, of those treated by plating 266 days, and of those treated by external skeletal fixation 370 days.

All patients treated by external skeletal fixation used a brace. Six of 17 patients treated by internal fixation did not use a brace, 3 of these used crutches and 2 remained in bed for several weeks without other protection before walking. One of these 6 patients walked without protection immediately after removal of the cast. The other 11 wore an ischial bearing brace. Twenty of the patients treated by traction used ischial bearing braces. Three patients used no brace but remained in bed without other protection for several weeks before beginning free weight bearing.

PERIOD REQUIRED FOR ROENTGEN EVIDENCE OF BONY UNION

Statements are seen that bony union of a fractured femur occurs in three to four months. This may happen exceptionally but is far from the rule in the adult. Good bony callus frequently does appear in this time, but until solid bony union occurs refracture is always a possibility. The criteria for bony union are (1) obliteration of the fracture line and (2) reestablishment of bony trabeculae.

By these criteria the shortest period required for bony union in this group was 155 days, which resulted in 1 patient treated by traction. One patient treated by internal fixation had roentgen evidence of bony union in 163 days. The shortest period for bony union in a patient treated by external skeletal fixation was 270 days. This unfavorable discrepancy is probably attributable to the fact that slight distraction of the fragments was a common concomitant in this type of treatment.

The longest period for bony union to occur in a patient treated with traction was 378 days. A patient who developed a nonunion after internal fixation required a bone graft and took 600 days to obtain a bony union. Another patient treated by external skeletal fixation took the inordinately long time of 505 days to show roentgen evidence of bony union. In this patient, distraction of the fragments early in the treatment was undoubtedly a factor in delaying union.

The average period for roentgen evidence of bony union in 23 femurs treated by traction was 233 days, almost eight months. In 17 patients treated by internal

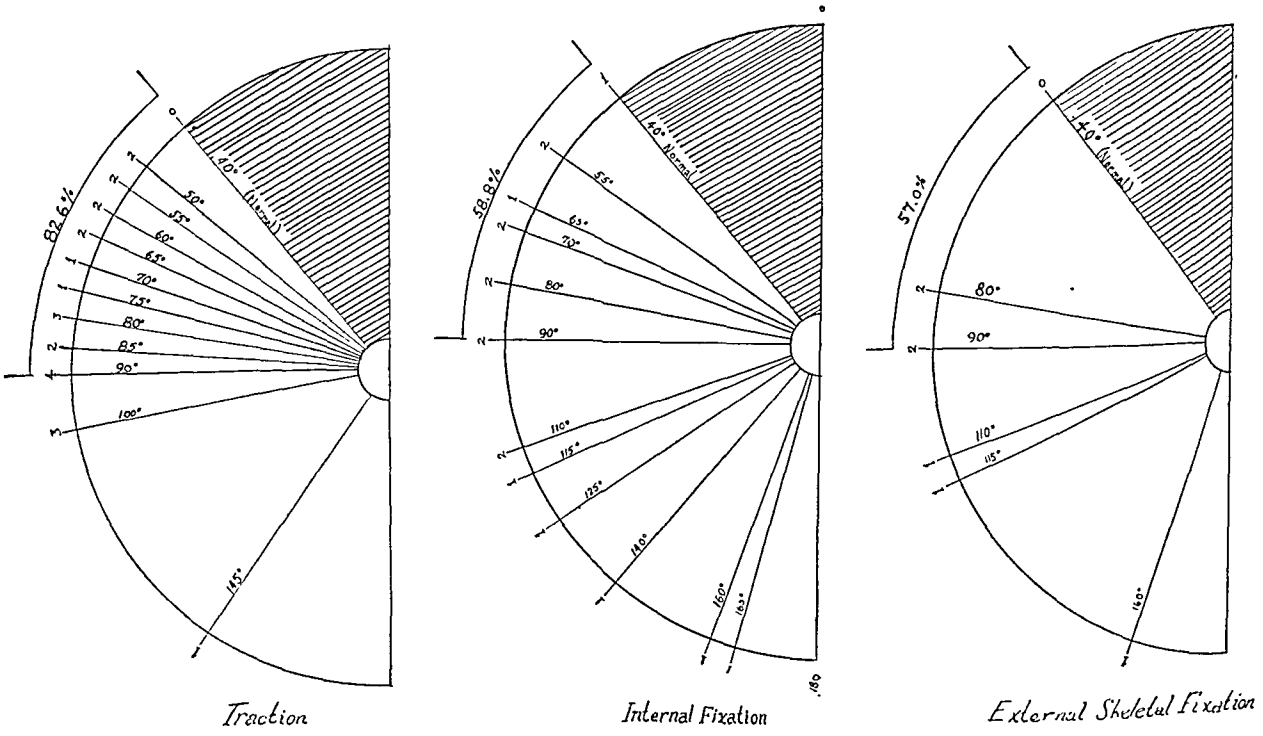

Fig. 5.—Individual range of knee flexion.

fixation it was 303 days, or ten months. In 7 patients treated by external skeletal fixation it was 374 days, or a little over twelve months.

As judged by x-ray evidence of bony union, traction was the most satisfactory method of treatment. This is consistent with the finding that it did not increase the period of total protection.

In this group of patients the period of enforced recumbency, the time required for bony union, and the total necessary period of protection do not condemn traction but rather establish it as the method likely to result in the minimum of economic dislocation.

STATUS OF JOINTS OF FRACTURED EXTREMITY

The most frequent and severe disability following in the wake of fracture of the shaft of the femur is loss of knee motion. The advocates of internal fixation and of external skeletal fixation stress the fact that these methods result in more nearly normal function of the knee. This may be true when a diligent regimen of after-care is carried out, but certainly it does not follow unless the surgeon is skilled in the postoperative management of the patient.

Of this entire group of patients, over the period during which they were observed, only 1 patient had an absolutely normal knee. This was a patient treated by internal fixation, who at the end of a year had a normal range of extension and flexion of the knee.

Loss of extension was not common and was usually of minor degree. A patient treated by traction had a loss of 5 degrees of extension at the end of a year. A patient treated by internal fixation had a loss of 20 degrees of extension and another had a loss of 5 degrees of extension. The patient with the severe loss of extension had suffered a complicating osteomyelitis. The other had been immobilized almost a year because of a bone graft following a nonunion.

No patient treated by external skeletal fixation suffered any loss of extension and all could completely straighten their knees.

Forty-six of the 47 patients had some degree of restriction of flexion in the knee over the period they were observed. Some of these will ultimately gain normal flexion with months of activity, but a very high percentage will have some permanent loss of knee bend (fig. 5).

The average arc of flexion of the knee in 23 patients treated by traction was 101 degrees; that is, the leg could be bent so that it made an angle of 79 degrees with the thigh. In this group the worst knee bent to an angle of 145 degrees and the best knee bent to an angle of 50 degrees.

The average arc of flexion of the knee in 17 knees treated by internal fixation was 85 degrees; that is, the leg could be bent to an angle of 95 degrees with the thigh. In this group the worst knee bent to an angle of 165 degrees and the best knee had normal motion (fig. 6).

The average arc of flexion of the knee in 7 patients treated by external skeletal fixation was 78 degrees; that is, the knee could be bent to an angle of 102 degrees with the thigh. The worst knee in this group bent to an angle of 160 degrees and the best knee to an angle of 80 degrees.

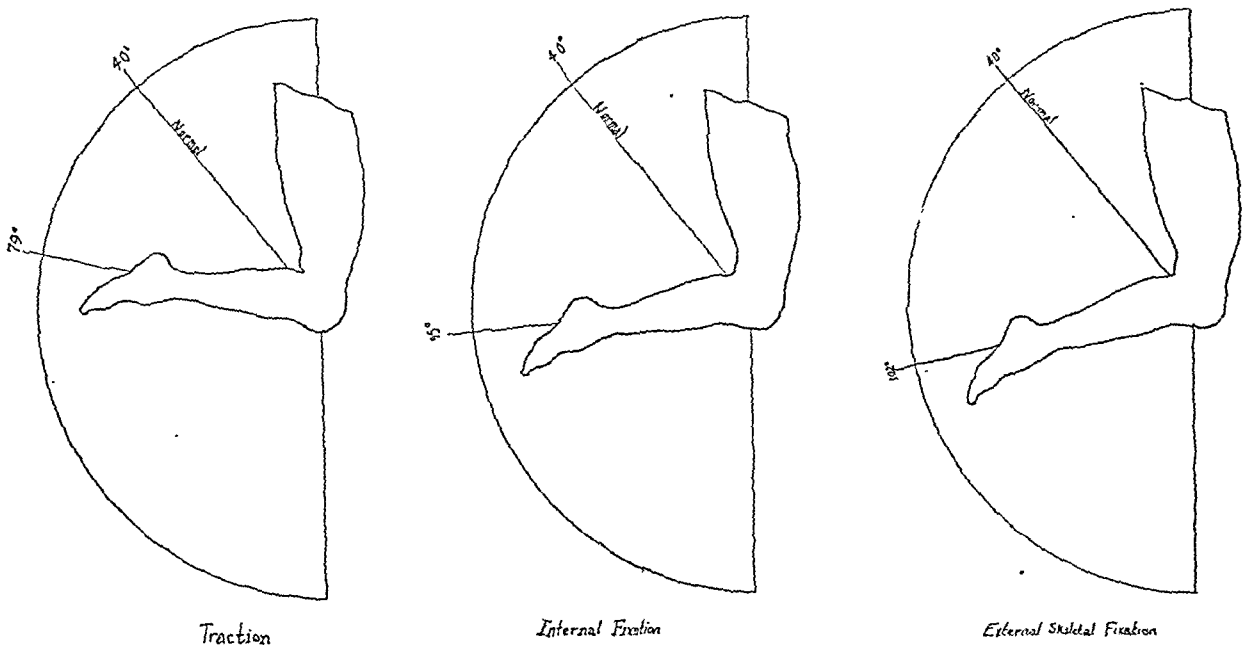

Fig. 6.—Average range of knee flexion.

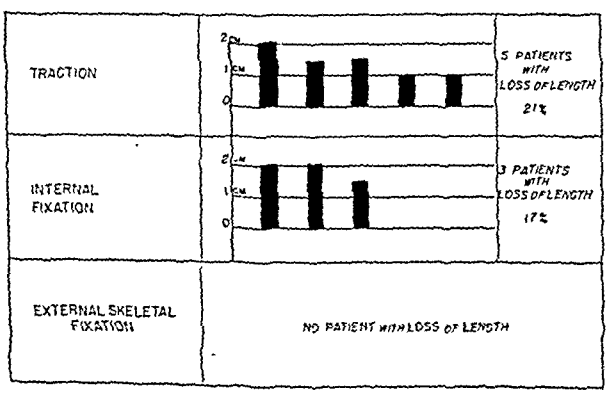

Fig. 7.—Patients with loss of length.

Eighty-two per cent of patients treated by traction could bend their knees to a right angle or better. Only 59 per cent of those treated by internal fixation could

bend the knee to a right angle, and right angle flexion was possible in only 57 per cent of those treated by external skeletal fixation. This is important, since the great majority of knees which reach right angle flexion will continue to make a slow steady gain, and an individual can carry on well in most activities with this range of motion.

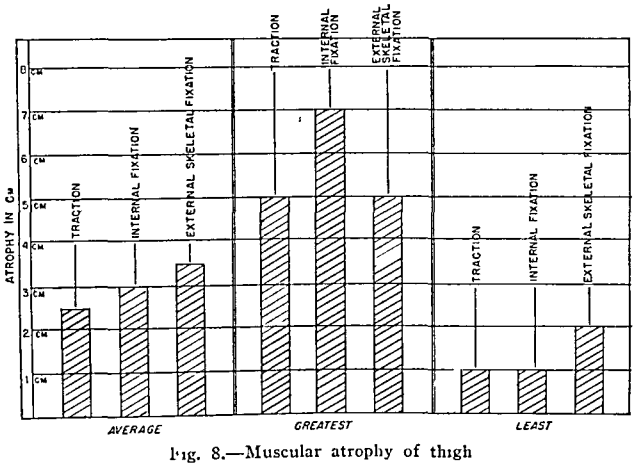

Fig. 8.—Muscular atrophy of thigh

No patient treated by traction had any loss of motion in the hip, ankle or foot. A patient treated by internal fixation who developed an osteomyelitis had an appreciable loss of rotation in the hip joint and 2 patients treated by this method, whose recovery was complicated by thrombophlebitis, developed troublesome swelling of the ankle and stiffness in the foot. A patient treated by external skeletal fixation had an appreciable loss of rotation in the hip and another had moderate stiffness in the ankle.

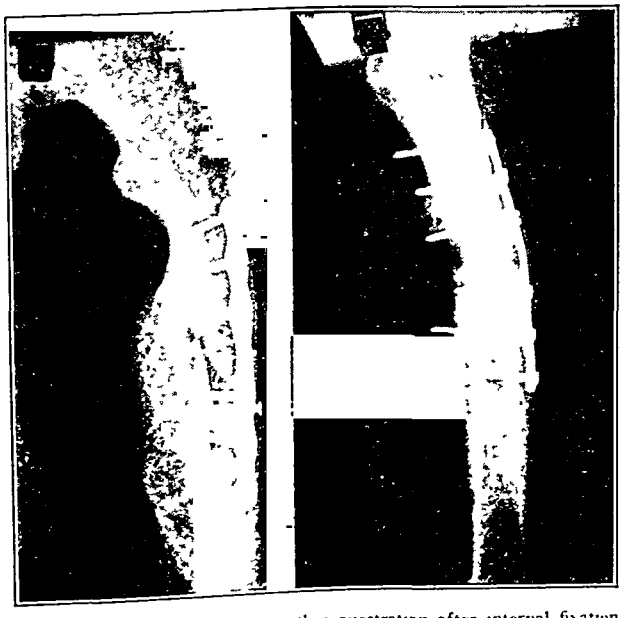

Fig. 9.—Severe osteomyelitis with sequestration after internal fixation. Saucerization necessary.

SHORTENING OF THE EXTREMITY

Five patients treated by traction, or 21 per cent, had some degree of shortening of the injured leg. In only 1 patient was this shortening of an adequate amount to produce disability. This patient had 2 cm. loss of length. Two other patients had 1.5 cm. loss of length of the leg, and the extremity of 2 patients was short by 1 cm. Of the 17 patients treated by internal fixation there were 3 patients who presented short legs. Two of these patients had a leg 2 cm. shorter than the uninjured leg. In 1 of these the shortening was due to the plate's breaking with resultant overriding, and the other patient lost length as a result of a nonunion, which required a bone graft. A third patient presented 1.5 cm. shortening. This was due to angulation from bending of the plate.

No patient treated by external skeletal fixation had any loss of length in the fractured extremity (fig. 7)

MUSCULAR ATROPHY

In the 23 patients treated by traction, the average loss of circumferences of the thigh due to muscle atrophy was 2.6 cm. The most severely affected patient in this group had a wastage of 5 cm. No patient had normal thigh muscles, and the least affected had only 1 cm. atrophy.

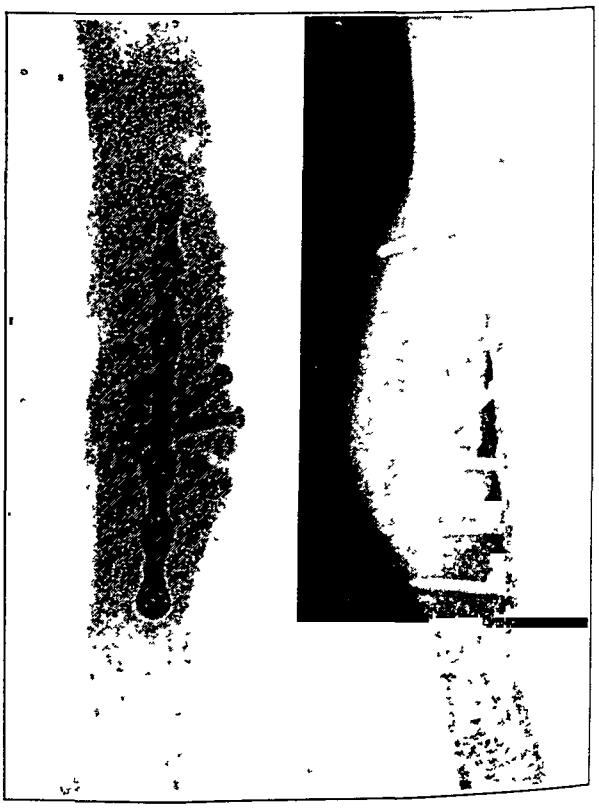

Fig. 10.—Pseudoarthrosis after internal fixation. Bone graft necessary. Patient terminated with 2 cm. shortening of leg

Of the 17 patients treated by internal fixation, the average loss of thigh circumference was 3 cm. The most severely affected thigh had shrunk 7 cm. subsequent to complicating sepsis. Another had shrunk 5 cm. One thigh had wasted only 1 cm. (fig. 8).

Of the 7 patients treated by external skeletal fixation, the average loss of thigh circumference was 3.5 cm. The greatest loss in circumference was 5 cm. and the least affected thigh in this group had shrunk only 2 cm.

Thus in judging the results of treatment by disability resulting from shortening of the extremity, from loss of motion in the knee and other joints and from the

degree of muscular atrophy in this group of patients, both external skeletal fixation and internal fixation with plate and screws were definitely inferior to traction.

COMPLICATIONS OF TREATMENT

Complications were most prevalent in the group of patients subjected to open reduction and internal fixation. Nine of 17 patients treated by this method, or 53 per cent, developed some complication. Moreover, this is the only group of patients in which any complication was of sufficient gravity to threaten the life of the patient. A patient developed a severe postoperative infection with an extensive osteomyelitis and thrombophlebitis and was critically ill for weeks. Another patient developed a severe osteomyelitis, and a third patient suffered a severe thrombophlebitis with pronounced febrile reaction, shortly after surgery. Another patient developed a severe postoperative infection but escaped without extensive osteomyelitis. However, several months later the plate had to be removed because of persistent drainage due to infection about a screw.

Fig. 11.—Broken plate, with shortening and delayed union in patient treated by internal fixation.

TABLE 3.—*Complications*

	Traction (23 Patients)	Internal Fixation (Plate) (17 Patients)	External Skeletal Fixation (7 Patients)
[illegible]	3 (13%)	9 (53%)	4 (57%)
	20	8	3
	0	2	0
	0	2	0
	0	2	0
	2	0	4
	Large pins		patients 12 of 23 pin sites
Nonunion	0	1	0
Late drainage from plate	—	3	—
Broken plate	—	1	—
Bent plate	—	1	—
Peroneal palsy	1	0	0

Complications which did not threaten survival were also prevalent in this group. A patient developed a pseudarthrosis at the fracture site. Three patients presented late drainage as a result of mild infections about the screws, with loosening of the plate. In 1 patient the plate broke and in another patient the plate bent (figs. 9, 10 and 11). This is a truly imposing incidence of complications, the gravity of which should make any surgeon hesitate to employ this method unless absolutely indicated.

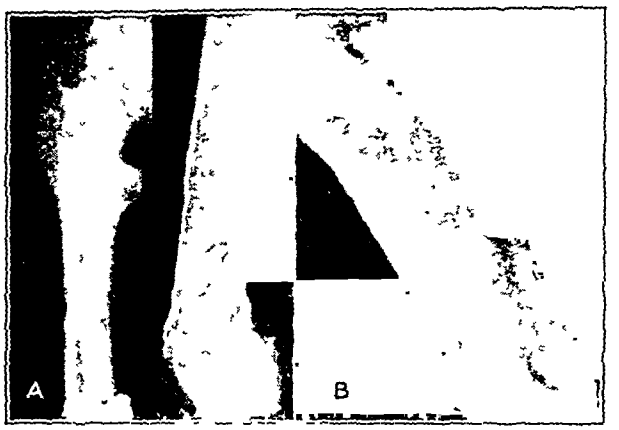

Fig. 12.—*A*, osteomyelitis of fixation pin sites in patient treated by external skeletal fixation. *B*, thigh after saucerization of trochanteric area and sequestrectomy of supracondylar pin hole which were necessary to terminate drainage.

In the group of patients treated by external skeletal fixation the incidence of complications also ran high, occurring in 4 of the 7 patients. In none of these patients was the complication a threat to life. The only complication in this group was osteomyelitis about the pin holes. This occurred in 12 of 23 pin holes. It was not seepage, but osteomyelitis, manifested by x-ray findings. This osteomyelitis was particularly severe in the trochanteric region and in the transfixed supracondylar region. The large pin, plus motion, resulted in stubborn infection of the cancellous bone. In 1 patient saucerization of the trochanteric area was necessary before drainage could be terminated. This patient was disabled eight months as a result of this complication (fig. 12).

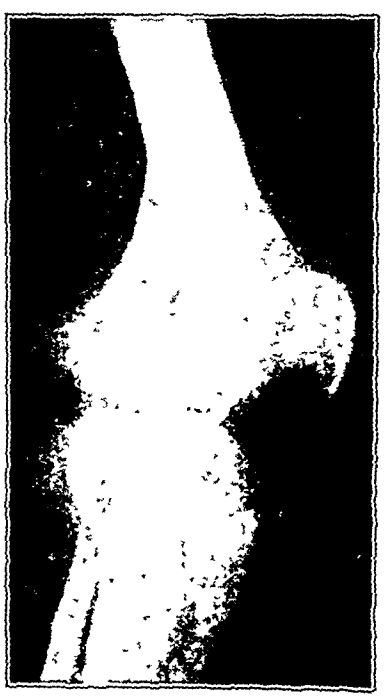

Fig. 13.—Ring sequestrum in femur of patient treated by traction with large pin. Pin placed incorrectly. The knee joint fortunately escaped infection.

In the group of 23 patients treated by traction, 3 patients, or 13 per cent, presented complications. Two patients developed localized osteomyelitis about the pin hole which required sequestrectomy. In both patients

a large Steinmann pin had been used. Neither involved the knee joint. No patient who had traction by a Kirchner wire developed infection in the bone. A patient developed a peroneal palsy which was transient and recovered spontaneously in three months (fig. 13).

OPERATIVE PROCEDURES NECESSITATED BY COMPLICATIONS

Six additional operative procedures of extensive magnitude and with some risk of their own were necessary for the 17 patients treated by open reduction and internal fixation. Two patients underwent the removal of the plate and an extensive sequestrectomy and saucerization of the femur. A patient had a bone graft of the femur. Three patients required the simple removal of the plate and screws (table 4).

Only one operation of major magnitude was necessary for patients treated by external skeletal fixation. This patient had an ostectomy and saucerization of the trochanteric area of the femur. Three other patients required sequestrectomy of one or more pin holes. In all, twelve of twenty-three pin holes required surgical attention.

In no patient treated by traction was the necessity for a surgical procedure of major importance created. Two patients required a sequestrectomy of one pin hole.

TABLE 4.—*Patients Requiring Operations Because of Complications*

Operations	Traction (23 Patients)	Internal Fixation (Plate) (17 Patients)	External Skeletal Fixation (7 Patients)
Sequestrectomy of pin holes	2	—	3 patients 12 pin holes
Removal of plate and sequestrectomy	—	2	—
Removal of plate	—	3	—
Bone graft	—	1	—

CONCLUSIONS

1. Fracture of the shaft of the femur, regardless of the method of treatment, is the cause of a long period of disability and frequently results in some degree of permanent disability.

2. The safest method of treatment of this fracture for the average surgeon in the average hospital is traction.

3. The election of traction methods to the exclusion of other types of treatment, by the average surgeon, will result in a shorter period of disability for the patient, better end results and fewer complications.

4. Failure to obtain absolute anatomic position of the fragments by x-ray is not an indication for open reduction. Under average circumstances open reduction should be reserved for those patients in whom there is well founded evidence of soft tissue interposition, after a trial of treatment by traction.

5. The general use of apparatus designed for external fixation and ambulation is likely to delay union and carries a great risk of producing osteomyelitis at the sites of the fixation pins.

Medicine an Observational Science.—In medicine we have a unique advantage in this respect over the purely experimental scientist in that medicine, while becoming increasingly an experimental, has long been and must continue largely to be an observational science. In its observational aspect it deals with a supremely difficult material under conditions that make constant demands on intuition and judgment.—Walshe, F. M. R.: The Integration of Medicine, *Brit. M. J.*, May 26, 1945.

CARCINOMA OF THE ORAL CAVITY

A TEN YEAR SURVEY IN A GENERAL HOSPITAL

EDWIN A. LAWRENCE, M.D.
AND
PHILIP S. BREZINA, M.D.
NEW HAVEN, CONN.

Carcinoma of the oral and pharyngeal mucous membranes comprises 3 per cent of all cancer and accounts for approximately 3,700 deaths yearly in the United States registration area. It is usually considered accessible cancer as contrasted to similar disease of the internal organs; yet the five year survival rates for it in this location are no better than for disease in some of the more inaccessible organs, such as the cecum and the large intestine. There are only a few large centers throughout the country limiting their work to the treatment of cancer and therefore it is treated for the most part in general hospitals. The excellent detailed reports from such specialized institutions as the Memorial Hospital of New York City are well known but perhaps do not give as clear a picture of the results obtained in a general hospital as might be desired.

Our purpose in this communication is to report a consecutive series of 145 cases of carcinoma of the oral cavity seen at the New Haven Hospital from Jan. 1, 1931 to Dec. 31, 1940 inclusive. The New Haven Hospital is a 510 bed institution serving an urban community of approximately 228,000 individuals in which during the decade under consideration there were approximately 625 practicing physicians and 210 dentists. If the two other hospitals in the city treated a similar number of persons in the same decade, a total of 435 people were afflicted with this disease in this period in the city. As the other institutions are somewhat smaller than the New Haven Hospital, it is highly unlikely that this was actually the case, and it is probable that the figure 350 would more closely approximate the number of patients treated. Moreover, many of these patients were referred from communities outside the city, and therefore the number seen by the professional men within the city and referred to the hospitals for treatment is undoubtedly less than 350. In other words, any given practicing doctor or dentist cares for an insignificant number of these persons in a lifetime of practice, and perhaps lack of familiarity with the disease and its management is an important factor in the poor results. There also may be a widespread, fatalistic tendency to give up in despair when such a disease is encountered. We do not deny that these tumors are difficult to handle, but this does not justify pessimism and should stimulate greater efforts toward earlier diagnosis, more intensive therapy and closer follow-up care. This study was not designed to analyze data such as sex incidence, nationality, age distribution and the incidence of various precancerous lesions such as leukoplakia, all of which are well known and have been discussed elsewhere; but to give the results of treatment, to discuss the causes of failure and the reasons for good results, and to suggest ways whereby the results might be improved. For this reason the group "primary admissions with treatment" has been established. To obtain this group it was necessary to exclude not only the patients who had received their initial treatment elsewhere and who came to this hospital

From the Department of Surgery, Yale University School of Medicine.
This investigation has been aided by a grant from the Jane Coffin Childs Memorial Fund for Medical Research.

for further treatment or consultation but also the patients who were in the "primary admission" class but who had either refused treatment or who had not been given treatment other than supportive because of far advanced disease. In other words, we were interested primarily in the results of our own therapeutic methods. The "secondary admission" class, the group of patients who came to New Haven Hospital after having been treated elsewhere, has been omitted from the final statistics.

The distribution of the cases is indicated in table 1. The largest group from the point of view of numbers was the hypopharynx and posterior tongue. Anatomically this consists of all tumors in the pharynx lying between the circumvallate papillae of the tongue and the extrinsic larynx. The anterior tongue group consists of all tumors of the tongue anterior to the circumvallate papillae; the floor of the mouth, of tumors in an area bounded laterally and anteriorly by the inferior alveolus and medially by the tongue; the alveolus, both upper and lower gum margins; the buccal mucosa, the mucous membrane lining of the cheeks and inner lips; the palate, both soft and hard palate; and the tonsil, tumors originating in the tonsillar fossa. There were a few cancers of the oral pharynx that were so extensive and involved such a large area (palate, tonsil, base of the tongue and floor of the mouth, for example) that they were difficult to classify as to the point of origin. Therefore, since they would have formed such a small group as to be completely meaningless, they were placed in the major groups according to where the bulk of the tumor lay.

The results are also shown in table 1. The best survival rate was obtained in the anterior tongue and buccal mucosa groups and the worst in the hypopharyngeal section. The comparative survival rates are similar to those quoted by Martin and his colleagues,[1] who have reported a 30 per cent five year survival rate for the buccal mucosa, 25.7 per cent for the alveolus, 25 per cent each for the tongue and the floor of the mouth, 19 per cent for the palate and 18 per cent for the tonsil. Richards [2] also indicates that carcinomas of the buccal mucous membrane and tongue are treated more successfully than in other locations in the oral cavity, although in this series of papers he does not give five year survival rates.

When carcinoma invades the local lymphatic system the treatment is always much more difficult, the prognosis more grave. It is generally considered that the five year survival rate when the lymph nodes are involved will be 50 per cent or less of that obtained when the lymph nodes are free of disease. Seventy, or 65 per cent of the total group of 108 (table 2), had lymph node involvement on admission or developed it at a later date, and only 4 of these, or 5.6 per cent, survived five years. On the other hand, 13 patients, or 35 per cent of the 37 patients who never had lymph node disease, were living at the end of five years. The highest rate of lymph node involvement occurred in the tonsil and hypopharyngeal groups, thus complicating already difficult therapeutic problems. An additional complication in the floor of the mouth and in the alveolus groups was direct extension of the disease into the adjacent mandible as determined by roentgenograms. Thirty-five per cent of the former group and 71 per cent of the latter were so involved.

TABLE 1.—*Oral and Pharyngeal Carcinoma, New Haven Hospital, 1931-1940 Inclusive.*

	Hypopharynx and Posterior Tongue	Anterior Tongue	Floor of Mouth	Alveolus	Buccal Mucosa	Palate	Tonsil	Total

* Four patients are alive and well from three to five years; 1 anterior tongue, 1 hypopharynx, 1 floor of mouth and 1 palate.
† This patient is living with the disease.

The treatment of carcinoma in the mouth and pharynx is essentially a radiologic problem, since only a small number of cases are entirely suitable for surgery. There were only 3 patients in the five year survival group who were treated entirely with surgery. One was a young woman with a malignant papilloma of the tongue that was excised. The 2 others were patients with cancers of the buccal mucous membrane. In 1, local excision of the tumor was done and, in the other, local excision with a radical neck dissection was performed. All of the others were treated either with x-rays alone or with x-rays in combination with radium or radon. It seems imperative that, if a cancerocidal dose of radiation is to be delivered into the tumor, a tumor dose of 5,000 roentgens or more must be administered. The roentgen therapy department at the New Haven Hospital treats with x-rays to skin toleration with multiple external fields and, after the tumor has shrunk to its maximum degree as a result of this treatment, inserts interstitial radon so that the total tumor dose will be at least 5,000 roentgens. In the early years of the decade under discussion, however, many of the patients were totally inadequately treated according to present standards, and probably some could have been saved had they received adequate therapy.

There seem to have been several causes for failure. One of the most important, of course, is the frequency

of lymph node involvement, which complicates the therapeutic program. It has been pointed out that 70 patients, or 65 per cent of the total group of 108, ultimately had lymph node involvement, as proved by biopsy or by the course of the disease. Eighty per cent of these 70 patients had disease in the lymph nodes at the time of admission, and 20 per cent of them developed metastases at a later date. In the early years of the period under discussion the management of this complication was inadequate and consisted of doses of radiation that are now considered much too small. In later years it has been the custom to manage these lymph nodes, in general, according to the indications and contraindications suggested by Duffy[3] for carcinoma of the tongue except that metastatic disease from carcinoma of the posterior tongue and hypopharynx is considered entirely a radiotherapeutic problem. Only 4 of these patients in this group have been salvaged. If one is to treat metastatic disease successfully, then a radical neck dissection must be done early provided the indications are met, but, if they are not, then heavy doses of radiation must be used. It is now the custom to cone down on the involved node and to give x-ray radiation to toleration. This is followed by interstitial implantation of radon so that the tumor dose will be 5,000 or more roentgens.

* This patient is living with the disease.

Another important cause for failure was inability to control the primary lesion. In table 1 it is pointed out that in only 35 of the 108 patients was the primary permanently controlled. The best results were obtained in the floor of the mouth, where the primary tumor was successfully and permanently controlled in 59 per cent of the 17 cases. The poorest results were in the palate, where only 2, or 18 per cent, of the 11 patients had permanent control of the primary tumor. As has already been stated, the principal cause for this failure was inadequate therapy, both surgical and radiologic, in the early years of this study. However, there are primary sites of oral carcinoma which are notoriously difficult to handle under any circumstances. The hypopharynx is such a region. Its vascularity, its rich lymphatic plexus and its inaccessibility as compared to other portions of the mouth and pharynx all contribute to this problem.

3. *Duffy, J. J.:* Cervical Lymph Nodes in Intraoral Carcinoma: Surgery or Irradiation? Am. J. Roentgenol. 39: 767-777, 1938.

Another factor which may be a cause of failure is delay on the patient's part in seeking treatment. This may not be as important as it at first seems and may be overshadowed by the inherent growth potentials of some tumors. It may account for the observation that occasionally a patient has symptoms for only a few weeks from a relatively small lesion, yet when the patient comes for treatment it is impossible to control the carcinoma by any known method, and it continues to grow rapidly with early death of the patient. If delay is arbitrarily defined as a period of more than two months elapsing between the time when symptoms first appear and the time when treatment is sought, then 65 per cent of the patients in the primary admissions group delayed. On the other hand, exactly the same proportion (65 per cent) of the patients who survived five years delayed more than two months before coming for treatment. This seems to be significant and furnishes food for thought when one considers the amount of work being done to have patients treated early.

Success in treatment is difficult to estimate. It can be defined in two ways: successful palliative management of a patient who from the first has an obviously hopeless tumor and in whom it is hoped only to obtain palliation; or it can be measured in terms of five year survival, which is the customary manner of gaging the effectiveness of therapy. Perhaps the two types of patients (the one with a hopeless tumor and the one with a hopeful lesion) should never be segregated from the point of view of management. Perhaps better success would always be obtained if one never allowed the thought of palliation alone to enter into the plan of treatment even though the disease seems to be advanced to a hopeless point. When the group of patients who have survived five years or more was analyzed in an attempt to determine reasons for the success in this group where treatment failed in the others, it was impossible to reach definite conclusions. An interesting observation was made, however, and will be illustrated by the following 3 cases:

CASE 1.—A white man aged 40 was admitted complaining of dysphagia of seven weeks' duration and a lump in the neck of two weeks' duration. Examination showed a large ulcerating carcinoma of the left tonsil and an involved lymph node in the left side of the neck. The first step in therapy was to remove the lymph node for biopsy purposes. It contained metastatic squamous cell carcinoma. The primary tumor was treated with x-ray radiation over a period of twenty-seven days to two lateral neck ports, each of which was given 2,800 roentgens measured in air. No other therapy was administered to the neck. The patient is now alive and well nine years after treatment.

CASE 2.—A white man aged 65 complained of a mass in the side of the neck of six months' duration. It measured 3 by 2 inches. It was excised and contained metastatic squamous cell carcinoma. Two weeks later a tiny primary was finally found by repeated biopsies at the base of the tongue. It was treated with 2,660 mgh. of interstitial radium. The area in the neck from which the tumor was excised was then given 2,400 roentgens of x-rays, measured in air, over a seventeen day period. This was followed in eight days by 3,325 mgh. of interstitial radium. The patient is alive and well ten years later.

CASE 3.—A white man aged 65 complained of an ulcer on the side of the tongue of three months' duration. It measured 1 cm. in diameter. The material removed for biopsy showed squamous cell carcinoma, grade 2. The primary tumor was treated with an intraoral cone and was given 4,862 roentgens, measured in air. Five months later a lymph node appeared in the side of the neck. It was excised and showed metastatic carcinoma. No other treatment was given. The patient is alive without disease six and one-half years after the last treatment.

According to our present standards, these 3 patients were among the least systematically managed of any of the entire group, yet they survived. This fact seems to emphasize the point that success in treatment depends as much on the degree of autonomy of the tumor and the host resistance as it does on such factors as delay in seeking treatment, extent of the tumor at the time of admission, intensity of therapy and adequacy of the follow-up. The lymph node in case 1 showed a pronounced degree of stroma reaction and was similar in appearance to nodes that have received radiation.

Another interesting possible factor influencing the success of treatment is brought out in table 3. We have long felt that mouth infection has a great deal to do not only with the origin of carcinoma in the mouth and upper gastrointestinal tract but also in the success of its management. It is a well known general impression that carcinoma in these locations is much more common in persons from a poor economic class whose dental care is neglected than it is in those from economically successful groups. We do not believe that trauma such as the actual chronic irritation from tooth snags is nearly as important as is the presence in the mouth over a long period of time of chronic dental infection in the forms of caries, pyorrhea and gingivitis which is continually feeding a possible etiologic agent

TABLE 3.—*Condition of the Teeth*

Condition of Teeth	*Primary* Admission with Treatment (83 of 108 Reporting)	Five Year Survivals (16 of 17 Reporting)	Failures (75 of 91 Reporting)
Good	2 (2%)	2 (13%)	0
Fair	7 (8%)	3 (19%)	4 (5%)
Poor	50 (56%)	4 (25%)	46 (63%)
Edentulous	28 (32%)	7 (43%)	21 (29%)
Complete false dentures	2 (2%)	0	2 (3%)
Total	89	16	73

into the mouth and upper gastrointestinal tract. It is also our impression that patients who have serious mouth infection do poorly under radiation therapy. Table 3 demonstrates that only 10 per cent of the group reporting had fair or good teeth and 56 per cent had poor teeth. Thirty-two per cent were edentulous. Thirty-two per cent of those who survived five years had good or fair teeth, and 25 per cent had poor teeth. Forty-three per cent were edentulous. In the failure group 5 per cent had fair teeth, 63 per cent had poor teeth and 29 per cent were edentulous. It is interesting to note that the 2 patients who had good teeth survived. These data are based on the condition of the teeth reported on the patients' records at the time of their admission to the hospital or clinic. It was impossible in a follow-up study such as this to find out the duration of dental decay in the persons with poor teeth or the period of time between the onset of dental decay and complete dental extraction in the persons who were edentulous. Both of these points deserve further study directed toward the possible relationship of the prolonged presence of mouth infection and carcinoma of the mouth, pharynx and upper gastrointestinal tract.

COMMENT

The therapy of oral and pharyngeal carcinoma is a difficult and discouraging problem. There can be only rare individuals who are naive enough to believe that radiation therapy and surgery are ideal therapeutic instruments. Yet, until something better is discovered, these two methods remain our only hope of obtaining survivals in the treatment of this as well as other cancer. Until that method appears, attempts at improving our results must be directed not only toward the more intelligent use of these two instruments but also toward making them more available to the general public and practicing physicians at large and toward educating the public and physicians in the early signs and symptoms of this disease. Perhaps it is incongruous to suggest, in face of the fact that it has been pointed out that there was no more delay in the failure group than in the successful, that early diagnosis is important. However, it is a simple platitude that a small tumor is more easily and satisfactorily treated than a large one, and if these individuals could only be seen when the lesion is small there is no doubt that greater success would be obtained.' Seven of the 26 patients with carcinoma of the hypopharynx stated at the time of admission that their chief complaint was a lump in the neck. In other words, more than 25 per cent of the patients in this group were complaining of something which indicated that for practical purposes the disease was beyond the curable stage. What would have happened if they could have been discovered when the tumor was only 1 cm. in diameter? Probably the only way that this could have been done and the only way that it can be accomplished in the future is for every one to have periodic examinations by an experienced physician. This would be a tremendous undertaking. The supply of doctors even in the postwar era probably will not be sufficient to do it and do it capably. The point has already been made that most physicians see only a few of these tumors in a complete lifetime of medical practice, and the problem in education and training men and women to recognize these lesions is equally appalling. But what other ways do we now have for detecting early cancer than in educating the populace at large in the signs and symptoms of the early disease and in training physicians to recognize the early disease when it *has appeared and to treat it adequately?* None whatever. Perhaps the time will come when a simple chemical test will suffice for diagnostic purposes, but that time has not yet arrived. The same educational program must be intensified in the dental profession as well as in the medical profession so far as oral carcinoma is concerned. Thirty-seven of the patients in this series had been seen first by a dentist. Ten of the 22 in the alveolus group had been seen and treated by a dentist before being referred for medical care, and 8 of these had delayed for more than two months. One had been under active care for nearly a year and a half. If our primary objective were only to find and treat the disease before the regional lymph nodes become involved, the salvage would be large. A specific example is the anterior tongue group, in which only 2 of the 14 patients with lymph node involvement survived five years, whereas 3 of the 9 without node involvement were living and well at the end of the same period.

As far as therapy itself is concerned, probably the cardinal point in successful management is attention to detail. The utmost care must be used in localizing the tumor and involved nodes if present, in localizing the treatment ports, in directing the treatment beam precisely not only at the initial treatment but also at all others, in management of the radiation reaction and in securing frequent follow-up examinations in the early post-therapy months so that, if an extension or

recurrence appears, further treatment can be initiated promptly. The problem of dosage is not complicated. If epidermoid carcinoma is to be destroyed, a dose of at least 5,000 roentgens must be delivered into the tumor. This usually requires supplementary interstitial radon in addition to roentgen therapy. Ideally the x-ray treatment should be administered in about twenty-one treatment days, and radon should be inserted when the tumor has regressed to its maximum degree. We believe that radiation should not be delivered so rapidly or so extensively that it will produce a pronounced degree of tumor necrosis with infection, because it is our impression that infection stimulates tumor growth.

SUMMARY

1. In a consecutive series of 145 cases of carcinoma of the oral cavity seen in a ten year period at the New Haven Hospital, the best results were in the buccal mucous membrane and anterior tongue groups, in which a 23 per cent five year survival rate was obtained.

2. The poorest result was in the hypopharyngeal group, in which an 8 per cent five year survival rate was obtained.

3. The outstanding cause of failure was inability to control the disease once it had extended into the regional lymph nodes.

4. The signs and symptoms of early disease and the principles of adequate therapy must be emphasized in educating the public and in training physicians and dentists, if the survival rates are to be improved.

IS DIGITALIS INDICATED IN MYOCARDIAL INFARCTION?

JOHN MARTIN ASKEY, M.D.
LOS ANGELES
AND
LIEUTENANT OTTO NEURATH
MEDICAL CORPS, UNITED STATES ARMY

Whether digitalis is of benefit in myocardial infarction is not generally agreed on. Many cardiologists believe that it should be used for congestive failure associated with myocardial infarction and especially if the congestive failure occurs with auricular fibrillation, but others have expressed doubt as to its ultimate value. Levine [1] believes "it is more likely to do harm than good." Conner [2] says that "among clinicians, the opinion is almost always . . . held that digitalis is dangerous." Fishberg [3] attributes much of the disrepute that digitalis suffers in myocardial infarction to its use in the early stages of shock rather than during congestive failure. He emphasizes that the theoretical dangers of digitalis in myocardial infarction are the production of (1) ventricular fibrillation, (2) rupture of the heart, (3) embolization, the latter two, he believes, being due to the more powerful systole, or (4) coronary constriction. He states, however, that whether or not these dangers are actual can be established only by observation of a large number of cases.

MATERIAL

This paper deals with the effect of digitalis in a group of 84 patients with auricular fibrillation, out of 1,247 patients with myocardial infarction admitted to the Los Angeles County General Hospital. Forty-four patients received digitalis alone, and 40 received either quinidine alone, quinidine and digitalis or no medication at all (table 1). Thirty-two patients with both congestive failure and auricular fibrillation were treated with digitalis alone. Congestive failure and auricular fibrillation are cardinal indications for digitalis therapy, and the results in these cases should be significant as to the good or bad effects of digitalis in myocardial infarction.

SUDDEN DEATH

The relation of the type of medication to sudden death (ventricular fibrillation?) is shown in table 1. Apparently there was no greater hazard from digitalis than from other medication. The 3 cases of sudden death following the use of quinidine occurred in 2 patients with intraventricular block and in 1 patient with prolonged atrioventricular conduction occurring prior to the onset of auricular fibrillation. Quinidine is ordinarily contraindicated in such cases.

RUPTURE OF THE HEART

Fifty-six patients were given digitalis alone or in combination with quinidine; rupture of the heart occurred in 3 (5.3 per cent). Seventeen patients were given no medication; rupture occurred in 1 (5.8 per cent). Digitalis apparently had no significant causative effect in these cases.

EFFECT OF DIGITALIS

Mortality and Types of Death.—The effect of digitalis on the 84 patients with auricular fibrillation was studied on two groups, one with congestive failure (48 cases) and one without congestive failure (36 cases). As "increasing congestive failure" and "progressive failure" are essential criteria of most cardiologists for the use of digitalis in myocardial infarction, only patients with liver enlargement and ankle edema were included in this group. Digitalization in most cases was fairly rapid, averaging 24 to 30 grains (1.5 to 2 Gm.) of the powdered leaf in three to four days. Thirty-two of the 48 patients with congestive failure received digitalis alone (table 2). Sixteen received other medication. Thirty-one of the 32 patients with congestive failure receiving digitalis alone died (96.8 per cent). Eleven of the 16 with congestive failure receiving other treatment died (68.7 per cent). Clinically recognized fatal embolism in the greater circulation occurred in 13 of the 31 who died in the group that received digitalis alone. Of the 13 with fatal emboli, in 7 emboli occurred in the cerebral circulation, in 5 in the femoral artery and in 1 in both the cerebral and femoral arteries. None of the 16 receiving other treatment had fatal embolism in the systemic circulation. In the 36 patients without congestive failure, digitalis alone produced no greater incidence of systemic embolism than did other types of treatment (table 3). Administration of digitalis alone seemed definitely associated with increased mortality and with increased systemic embolism in those with congestive failure but not in those without congestive failure. Because we were interested specifically in the effect of digitalis on intracardiac thrombosis, embolism in the greater circulation only was considered. Sudden hemiplegia, or sudden arterial obstruction in an extremity, if due to emboli from

intracardial thrombi, can arise only from emboli from the left side of the heart, save in the paradoxical embolism due to anomalies of the cardiac septums. Pulmonary embolism may often be due to peripheral venous thrombi. According to these data the danger of giving digitalis in myocardial infarction was not the danger of inducing ventricular fibrillation and sudden death or of producing cardiac rupture. The danger was not apparently in its administration to patients without congestive failure but was in the administration to patients with the cardinal indications for digitalis, those with congestive failure and auricular fibrillation.

HAZARD OF EMBOLISM

The hazard of giving digitalis, apparently, was chiefly the hazard of embolism. Embolism in the systemic circulation is dependent on the presence of mural thrombi in the left side of the heart and on a mechanism that releases them. The exact mechanism by which the

digitalis effect was exerted in producing the increased incidence of embolism is difficult to be certain about. Many factors are involved in the formation and dislodgment of the intracardiac thrombi. The group of cases in which digitalis was a hazard, that is, those with congestive failure, was the group which would naturally have a larger number of preexisting mural thrombi than the group without congestive failure and thus have more potential emboli. They were the ones with preexisting cardiovascular disease, often previous infarction and a longer standing auricular fibrillation which usually persisted.

IMPORTANCE OF PREEXISTING MURAL THROMBI

The importance of preexisting mural thrombi in producing embolism, and particularly the importance of the duration of auricular fibrillation in producing the thrombi, is suggested by the high incidence of fatal emboli in the group of 8 patients in whom auricular fibrillation had been known to exist before the onset of myocardial infarction. Of the 7 who died, 5 died of emboli in the greater circulation (71 per cent). All of these 5 had been given digitalis alone and the auricular fibrillation had persisted until death by embolism.

The effect of old age in relation to mural clots[4] is evidenced by the increased age in this group. The average age was 70. The occurrence of systemic embolism was correlated also with the time of persistence of the arrhythmia following the attack of myocardial infarction. Of the 49 patients with auricular fibrillation persisting until death, 36 died in seven days or less and 13 died after seven days or more of the arrhythmia. Only 7 of the 36 (19.4 per cent) dying in the first week died of systemic embolism, whereas 9 of 13 dying after seven days of the arrhythmia died of systemic embolism (69 per cent).

Why did digitalis alone mobilize the thrombi in the patients with congestive failure, and not the other medication? Did it act by producing more potential emboli, that is, by forming more new mural thrombi or augmenting old intracardiac thrombi; or did it act by inducing dislodgment of the thrombi? Persistence of auricular fibrillation tends to produce new auricular clots and to augment old auricular clots. Digitalis ordinarily tends to fix and perpetuate the arrhythmia.[5] Theoretically the persistence of the arrhythmia should increase the number of potential emboli, which should be reflected by an increased incidence of actual emboli. All 13 of the patients with congestive failure who

number of intracardiac thrombi. de Takats [6] and Massie [7] recently have shown such an effect of digitalis. Theoretically, therefore, there are two effects of digitalis tending to produce mural thrombi and thus, by producing more potential emboli, tending to lead to a greater incidence of embolism. In the group with congestive failure examined at necropsy one would expect the patients who had received digitalis to show a higher incidence of mural thrombi than those receiving other medication. This was not found to be true (table 4). There was high incidence of mural thrombi regardless of the medicine. Perhaps this is too small a group to be significant. All those with congestive failure, however, had a high incidence of intracardiac thrombi (over 70 per cent). Only 7 of the 14 of the group without congestive failure examined at necropsy showed intracardiac thrombi.[8]

EFFECT OF DIGITALIS ON DISLODGMENT OF THROMBI

The effect of digitalis on heart size has been shown by Stewart [9] to vary, depending on whether or not congestive failure with an enlarged heart is present. A decrease in heart size occurred practically always when congestive failure was present but not necessarily when no congestive failure was present. If these data apply to our cases it may logically be inferred that the 39 patients with congestive failure receiving digitalis alone or digitalis and quinidine developed a decrease in heart size which did not occur with those not receiving digitalis or with those with no congestive failure who received digitalis. This action of digitalis on the enlarged heart, producing a slower stronger systole with a contraction in size of the ventricular cavity, theoretically could dislodge and expel a ventricular thrombus. Although the effect of digitalis in auricular fibrillation is essentially on the ventricle, Goodman and Gilman [5] say that the auricle is usually speeded both by the muscular and by the vagal effects. The composite effect of digitalis in congestive failure apparently is to expel thrombi. This mechanism could explain the high incidence of embolism in the patients with congestive failure. It is understandable but, from the standpoint of this problem, unfortunate that there are no accurate data as to the occurrence of emboli in congestive failure in heart disease in general with and without digitalis. The embolism occurring in patients with auricular fibrillation and congestive failure in heart disease without myocardial infarction possibly is the result of the expulsive action of digitalis on a heart with fewer mural thrombi than on the heart with myocardial infarction and thus fewer emboli. The incidence of embolism in such cases is so small in relation to the obvious benefit of digitalis that even though embolism admittedly was due to the drug it would be relatively negligible. In the patients with myocardial infarction whom we observed, the reverse was true. There was no obvious beneficial effect from the digitalis which outweighed the obvious harmful effect of producing embolism. Return of the sinus rhythm, formerly a supposedly notorious cause for dislodging auricular clots, occurs rarely after digitalis and was not a factor in our series. Only 3 of the 32 patients with congestive failure receiving digitalis alone returned to sinus rhythm.

Although the precise mechanism for the production of the increased embolism is not yet established, some deductions are justifiable in our cases. Congestive failure occurring in association with auricular fibrillation and myocardial infarction was associated with a very high incidence of mural thrombi (75 per cent) and the risk of fatal embolism after digitalis administration alone was very high. Digitalis apparently mobilized the thrombi in a dangerously high percentage, to such a degree that the risk of the drug became greater than the risk of the condition itself. Digitalis is particularly indicated in congestive failure of heart disease in general, but these results would seem definitely to impugn the congestive failure of auricular fibrillation occurring with myocardial infarction as an indication for the use of digitalis alone.

CONCLUSION

Digitalis alone used in congestive failure occurring with auricular fibrillation in myocardial infarction in 32 patients at the Los Angeles County General Hospital proved to be more harmful than beneficial. The hazard ordinarily considered the greatest, that is, the production of fatal ectopic ventricular rhythm with sudden death, was not in evidence. There was no increased hazard from cardiac rupture. The mortality was increased largely by the production of fatal emboli to the greater circulation. On the basis of these data, digitalis administered alone for the congestive failure associated with auricular fibrillation and myocardial infarction would seem contraindicated.

ACETYL-BETA-METHYLCHOLINE IN ADDISON'S DISEASE

GEORGE A. PERERA, M.D.
NEW YORK

It has long been established that the disturbances in water, electrolyte and carbohydrate metabolism in acute adrenal cortical insufficiency may be corrected by adequate replacement therapy. Under certain circumstances, however, sudden circulatory collapse and even death may occur in patients with Addison's disease despite control of these other factors. These circumstances notably include infections, minor traumatic injuries or operative procedures, and they sometimes take place without apparent cause.

Swingle and his associates [1] have pointed out that fatal collapse in adrenalectomized animals need not involve changes in salt and water balance. Loeb [2] has observed a number of patients with Addison's disease who died a typical addisonian death but without the characteristic chemical changes in the blood serum and while receiving desoxycorticosterone. He has suggested that a disturbance in vasomotor regulation, either peripheral or central, may be responsible and that this is

Dr. Robert F. Loeb made many constructive suggestions.
From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

not consistently controlled by the cortical hormones now available. Despite these speculations, systematic studies of autonomic responses in patients with adrenal insufficiency have not been carried out.

The present study was undertaken to compare certain pharmacodynamic responses in patients with adequately treated adrenal cortical insufficiency and patients without disease of the adrenal gland. For this purpose the reactions of these two groups to the administration of acetyl-beta-methylcholine has been observed.

METHODS

Acetyl-beta-methylcholine chloride[3] 2.5 mg. was administered subcutaneously to 10 hospital patients as controls and on six occasions to 5 patients with Addison's disease. The control group included only cases free of hypertensive vascular disease[4] and endocrine disturbances. The diagnosis in the addisonian group had been previously established in all cases in the wards of the Presbyterian Hospital. The clinical diagnosis was confirmed by the presence of a low sodium concentration of the blood serum during a crisis or as a result of the withdrawal of salt from the diet. The experiments with acetyl-beta-methylcholine were carried out at a time when serum sodium concentrations were between 136 and 140 milliequivalents per liter as calculated by the indirect method.[5] Four of the patients studied were being treated with desoxycorticosterone acetate,[6] with or without additional salt, and 1 was being maintained on salt alone.

The systolic pressure at the time observations were made was 104 mm. of mercury or higher in all but 1 of the addisonian group. Except for this patient, whose arterial pressure was 92/60, the blood pressures were entirely comparable in the two groups. The plasma volume was determined in 1 patient with the blue dye T..1824 on the day of injection and found to be within the estimated normal range based on body surface area.

All observations were made with the patients lying in bed with a 30 degree head gatch. Blood pressures were recorded every minute for at least ten minutes prior to the administration of acetyl-beta-methylcholine and until at least five successive readings showed a systolic and diastolic fluctuation of not more than 4 mm. of mercury. After injection, readings were made at half-minute intervals and the lowest systolic and diastolic levels recorded until values had returned to their initial levels. Because of the potential hazards of even such minor procedures in patients with Addison's disease, atropine was kept at hand for immediate hypodermic use and solutions of saline and glucose were available for intravenous injection.

RESULTS

In the 10 control patients a slight drop in blood pressure was observed two to four minutes following the subcutaneous injection of 2.5 mg. of acetyl-beta-methylcholine. The decrease averaged 6 mm. of mercury systolic, with even less diastolic change. In the control group subjective symptoms were minimal. Two patients noted a slight sense of warmth, and 1 complained of epigastric "rumbling." There was no significant change in pulse rate.

In contrast to the control group the subjective and objective effects in the patients with Addison's disease were much more pronounced and at times reached alarming proportions. Within two to three minutes after injection, blood pressures reached their lowest levels, the average systolic decrease being 22 mm. of mercury, the diastolic 19 mm. In association with this more pronounced hypotension all the patients noted flushing, sweating and a sense of increased peristaltic activity; 3 had loose bowel movements shortly afterward. A slight but definite tachycardia was the rule. The blood pressure returned to its initial levels within five to ten minutes after the injection.

Atropine sulfate in doses of 0.6 mg. was given subcutaneously to 2 patients with Addison's disease a few minutes prior to the administration of acetyl-beta-methylcholine. In these patients the effects of the acetyl-beta-methylcholine were blocked, the response being similar to that observed in the control group. In 1 patient with Addison's disease 0.3 cc. of 1:1,000 epinephrine hydrochloride was given hypodermically five minutes before acetyl-beta-methylcholine. Palpitation and tachycardia were noted, with a rise in blood pressure from 122/82 to 140/86. However, the response to subsequent administration of acetyl-beta-methylcholine was not altered. To exclude the possible effects of the hypodermic injections alone, 2 patients with adrenal cortical insufficiency received sterile water subcutaneously without significant change in blood pressure or the development of symptoms.

Effect of Acetyl-Beta-Methylcholine on Blood Pressure

Normals		Hypoadrenalism	
Before	After	Before	After
122/84	116/80	104/68	78/48
136/86	130/80	92/60	68/40
110/78	104/76	108/70	94/58
100/68	90/64	122/84	100/62
116/80	110/78	116/76	84/52
124/78	120/80	138/86	114/70
104/64	96/60		
100/74	94/60		
110/70	104/64		
116/74	114/70		
Mean Values			
114/76	108/71	113/74	91/55

In 1 addisonian patient a blood sugar value of 96 mg. per hundred cubic centimeters was obtained at the peak of the acetyl-beta-methylcholine response to indicate that hypoglycemia did not contribute to the symptom complex. As already stated, the plasma volume was determined in 1 patient on the day of injection and found to be within the estimated normal range. This measurement was undertaken to exclude the possibility that patients with hypoadrenalism were not more vulnerable, owing to a reduced circulating blood volume.

COMMENT

In Addison's disease, susceptibility to cold, acrocyanosis, venospasm following introduction of a needle (as judged by abnormally high venous pressures which fall after relaxation and the application of heat) and sudden circulatory collapse after comparatively minor stimuli are among the features not infrequently observed in patients in this clinic. These disturbances are encountered not only in the presence of patent insuffi-

ciency but also after electrolyte and water balance are restored to normal and when hypoglycemia is not present. This suggests that even in the adequately treated addisonian patient there exists a disturbance in the peripheral vascular system not corrected by the usual forms of therapy.

Although the lability of the peripheral vascular system may be due in part to faulty intermediate metabolism [1] or to some obscure cardiac factor,[7] some observers have noted a reduced sensitivity to pressor agents [8] and others have presented evidence of capillary dilatation and increased permeability.[9]

It has been possible in the present study to demonstrate a difference in the response of addisonian patients, maintained by salt or desoxycorticosterone, and certain nonaddisonian patients to the administration of acetyl-beta-methylcholine. The reaction of the group with hypoadrenalism was qualitatively similar to the control group, but the quantitative difference was striking. The specificity of the response was indicated by the fact that it could be minimized by the prelimiary administration of atropine.

Further evidence of the increased susceptibility of the addisonian group to acetyl-beta-methylcholine was afforded by the fact that the blood pressure of these patients and the control group was essentially the same before the injection of the cholinergic drug. The increased reaction to acetyl-beta-methylcholine could not be correlated with a deviation of the blood sugar or plasma volume from normal.

The apparent increased sensitivity of the addisonian group to parasympathetic stimulation cannot be attributed solely to a decrease in cardiac output, since increased intestinal peristalsis and flushing of the skin accompanied the fall in blood pressure and tachycardia.

CONCLUSIONS

1. Acetyl-beta-methylcholine 2.5 mg. subcutaneously given on six occasions to 5 patients with hypoadrenalism caused a pronounced blood pressure drop far out of proportion to that observed in 10 controls without adrenal disease.

2. Sweating, flushing and increased intestinal peristalsis accompanied the reaction in the group with Addison's disease, whereas associated symptoms were much less evident in the control group.

3. These abnormal responses in addisonian patients took place even though the patients were maintained in electrolyte and fluid balance and while receiving adequate therapy with salt or desoxycorticosterone.

4. The increased sensitivity of patients with treated Addison's disease to acetyl-beta-methylcholine suggests that in adrenal cortical insufficiency there is a defect in the response of the autonomic nervous system.

5. This defect may contribute to the inability of the treated addisonian patient to react normally to altered environment conditions or minor stimuli of many kinds.

Clinical Notes, Suggestions and New Instruments

KALA-AZAR (VISCERAL LEISHMANIASIS) SIMULATING SPLENIC ANEMIA

COLONEL JAMES S. SWEENEY, MAJOR RICHARD D. FRIEDLANDER AND LIEUTENANT COLONEL FRANK B. QUEEN
MEDICAL CORPS, ARMY OF THE UNITED STATES

Kala-azar (visceral leishmaniasis) is an infectious disease resembling clinically in many respects chronic malaria and undulant fever. It is characteristically associated with an irregular, recurring fever over a period of weeks, sometimes having a double daily rise, progressive enlargement of the spleen, followed by hepatomegaly, and usually later in the course of the disease anemia, leukopenia and progressive wasting. According to Manson-Bahr [1] the disease may vary a great deal in its onset. As stated in the beginning, it may be characterized by a chronicity simulating other prolonged recurring infectious diseases. On the other hand, in a small percentage of cases it may be characterized by a latency without symptoms and present its activity by an acute onset with predominantly abdominal symptoms, high temperature and associated toxic manifestations. The etiologic agent is Leishmania donovani, a protozoan organism which occurs in the Leptomonas (flagellate) form in the bodies of various insects and in artificial culture mediums. The vector is suggestively a blood sucking sand fly of the genus Phlebotomus. Also the disease may be possibly transmitted through the ingestion of food or drink contaminated with Leishmania donovani or by contact.

The disease is widespread and occurs in the Mediterranean countries, southern Russia, India, China, Manchuria, Abyssinia, Sudan, northern and eastern Brazil, the Chaco region of Argentina, the Paraguay-Brazil border and northern Bolivia. Its appearance in recent years in the Western Hemisphere has been limited to South America. Incidence of the disease in the United States has been limited to imported cases.[2] Indeed, kala-azar has been observed so infrequently in North America that it is rarely considered in this country as a cause of splenomegaly and the other signs and symptoms.

Recent importation of prisoners of war to the United States and the return of American soldiers from countries where leishmaniasis is endemic should stimulate current medical thought in this country as to the importance of this disease in future cases of unexplained splenomegaly and associated signs and symptoms. With this thought in mind the present case is reported.

REPORT OF CASE

An enlisted man aged 22, Italian, entered the Station Hospital at Hill Field, Utah, Sept. 26, 1944, complaining of severe left sided abdominal distress and distention of four days' duration.

His past history was essentially negative. He was born in Gravellona di Lomellina, province of Pavia, Italy, and except for frequent colds in childhood his health generally had been quite good. He entered the Italian army Jan. 15, 1942, at which time he weighed between 135 and 140 pounds (61 to 63.5 Kg.). While in Sicily in September 1942 he had an illness characterized by chills and fever for four days which was diagnosed as malaria. It subsided following the administration of quinine. There were no recurrences of this illness. On July 23, 1943 he was taken prisoner in Sicily by the American forces and eventually sent to the continental United States, where he became a member of an Italian service unit.

On admission to the Station Hospital the patient was malnourished and weighed about 110 pounds (50 Kg.). He appeared critically ill. His temperature was 100.8 F., the pulse rate was 112 and the respiratory rate was 20 per minute. The outstanding physical finding was confined to the abdomen,

1. Manson-Bahr, Philip: Synopsis of Tropical Medicine, Baltimore, Williams & Wilkins Company, 1943.

2. Mathieson, D. R., and Watson, B. A.: Kala-Azar, J. A. M. A. **112**: 308 (Jan. 24) 1939. Price, F. L., and Mayor, R. A.: A Case of Kala-Azar, ibid. **125**: 490 (June 17) 1944.

which was described as grossly distended, with pronounced tenderness and splinting, particularly on the entire left side. There was dulness on percussion in the left abdomen and flank.

Laboratory studies at this time revealed that the leukocyte count was 4,000, with 55 per cent polymorphonuclear cells, 35 per cent lymphocytes and 10 per cent monocytes. The urine showed a trace of albumin and numerous fine granular and hyaline casts. Repeated blood smear examinations for malaria were negative. Blood cultures were negative. The white blood cell count ranged from 2,600 to 6,200, with a tendency to a slight predominance of polymorphonuclear leukocytes. The hemoglobin varied between 60 and 80 per cent, and the red blood cell count ranged around 3,560,000. The sedimentation rate was 31 mm. per hour (Westergren method).

The patient continued to have considerable abdominal pain and distress, with an irregular febrile course and tachycardia, and because of this he was tentatively thought to have a peritonitis secondary to a possible splenic abscess. Glucose in saline solution was given intravenously, Wangensteen suction employed and oxygen inhalations administered. On September 29 penicillin therapy was started, 20,000 units every three hours intramuscularly for a total of 1,190,000 units. On September 30 plasma was given. On September 31, October 1 and October 4 transfusions of 500 cc. of citrated blood were given.

On October 8 the abdominal findings previously described were interpreted as a mass, most likely the spleen. By October 14 the patient's condition had improved. X-ray scout films of the abdomen were taken and revealed a large, soft tissue mass extending from the left diaphragm to just below the left iliac crest. This was considered to be the spleen, since the left kidney could be easily outlined beneath the mass. The patient's condition became stationary, and because of the diagnostic problem involved he was transferred to Bushnell General Hospital November 16 for further observation.

On this date the patient appeared cachectic, with a protuberant abdomen which at first glance suggested the presence of ascites. Palpation, however, disclosed the prominence to be due to a large firm, smooth mass occupying the entire left half of the abdomen, extending to the right of the midline into the pelvis just below the umbilicus (fig. 1). The lower pole of this mass in the pelvis was quite tender. There was no enlargement of the liver, nor were there any distended superficial abdominal veins. There was no lymphadenopathy nor icterus. There was pronounced wasting and atrophy of all skeletal muscles. There was no edema. The heart and lungs were normal. The pulse rate was 100, rhythm regular, blood pressure 95/70. The patient's height was 64½ inches (163 cm.). His nude weight was 111 pounds (50 Kg.).

Previous radiographic studies left little doubt as to the abdominal mass being the spleen. The case therefore became a diagnostic problem revolving about an enlarged spleen, associated anemia, cachexia, albuminuria and low grade fever. The possible diagnoses included the more likely causes of splenomegaly and embraced the following possibilities: Banti's syndrome ("Banti's disease"), thrombosis of the splenic vein, splenic infarction, leishmaniasis, schistosomiasis, chronic malaria, Hodgkin's disease, leukemia, primary neoplasm of the spleen, primary amyloidosis of the spleen, gumma or tuberculoma of the spleen.

Examination of the urine on entry showed a trace of albumin and 15 to 20 white blood cells per high dry field. Frequent urine examinations revealed a persistent, moderate albuminuria, low specific gravity with moderate numbers of red and white blood cells and hyaline and granular casts. Blood nonprotein nitrogen was 35 mg. per hundred cubic centimeters, plasma proteins 7.1 Gm. per hundred cubic centimeters, albumin 1.2 Gm. per hundred cubic centimeters, globulin 5.9 and 7.5 Gm. per hundred cubic centimeters with a persistently reversed albumin-globulin ratio. An intravenous phenolsulfonphthalein dye excretion test showed 57 per cent excretion of the dye in one hour and 27 per cent excreted in the first half hour. The sulfobromophthalein liver function test showed 32 per cent retention of the dye in the blood stream after five minutes and no retention after twenty minutes. The congo red test showed 20 per cent retention of the dye in the blood at the end of one hour. The icterus index was normal.

Examination of the blood revealed a hemoglobin of 9.8 Gm. (63 per cent), erythrocytes 3,480,000, reticulocytes less than 0.1 per cent, platelets 33,000, bleeding time eleven minutes, clotting time twelve minutes, prothrombin time 62 per cent of normal control, normal fragility test, hematocrit 32 per cent, sedimentation rate 125 mm. in sixty minutes and a leukocyte count of 4,100 with 56 per cent lymphocytes, 2 per cent monocytes, 1 per cent basophils, 39 per cent mature polymorphonuclear leukocytes and 2 per cent juvenile forms. Blood smears showed 53 per cent of the white blood cells to be peroxidase negative and 47 per cent peroxidase positive. Serologic tests of blood and spinal fluid were negative. Frequent smears of the blood were examined for malarial parasites and found to be negative also after the injection of epinephrine. Numerous smears were examined for Leishman-Donovan bodies in the circulating blood and bone marrow and were likewise negative. Because of consistently negative findings and inadvertence the formol-gel test was not done at this time. The tuberculin test gave a 4 plus reaction in forty-eight hours. Numerous stool examinations were negative for parasites. Agglutination tests for undulant fever were negative.

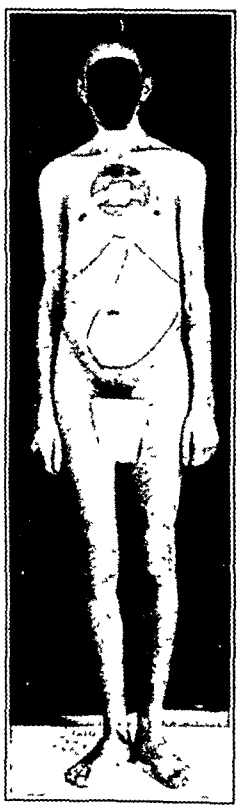

Fig. 1. — Appearance of patient, showing emaciation, generalized muscular atrophy and outline of enlarged spleen.

X-ray films of the skull, chest and pelvis for possible metastatic lesions were negative. A gastrointestinal series revealed no esophageal varices nor other abnormality of the upper gastrointestinal tract. A barium enema demonstrated a large extrinsic mass displacing the transverse colon and splenic flexure downward, occupying the left side of the abdomen and descending into the pelvis.

By December 8 the patient developed a pronounced leukopenia. The total white cell count dropped to 1,800 cells per cubic millimeter with 45 per cent polymorphonuclear leukocytes, hemoglobin 88 per cent (13.8 Gm.) and red blood cell count of 4,370,000. The gums began to bleed and appeared quite spongy. The blood ascorbic acid at this time was 0.2 per cent and appropriate vitamin therapy was initiated. The patient's general condition seemed to be slowly regressive. Splenic puncture was considered, but because of the danger of uncontrollable bleeding and the debatable nature of the splenic lesion exploration was agreed on. Between December 12 and December 14 the patient was given several transfusions of whole blood and 270,000 units of penicillin preceding surgery.

On December 14 laparotomy was performed under gas-oxygen anesthesia by Col. Henry G. Hollenberg and Major Clyde S. Roof. A long left rectus incision was made through which the enlarged spleen was palpated. It was relatively soft, with many fine adhesions. The liver, gallbladder and kidneys were normal. A few small nodes were present at the hilus of the spleen and later removed for biopsy. The incision was extended in both directions and transversely to the left in the form of a T. The perisplenic adhesions were broken by blunt dissection. They were particularly dense over the dome. There was considerable bleeding. The splenic vein was found to be free of thrombi. The splenic arteries were quite small. The pedicle was clamped and the spleen removed without undue difficulty. During and immediately after surgery the patient received 6,000 cc. of fluid, including plasma, whole blood and glucose in saline solution. The patient's postoperative course was a bit stormy for the ensuing twenty-four to thirty-six hours, but

with further supportive treatment his condition improved rapidly and was uneventful thereafter.

The spleen weighed 1,770 Gm. and measured 30 by 15 by 8 cm. (fig. 2). The external surface was mottled and gun metal gray. The capsule was thin. Over its surface were many small, fibrillar adhesions and irregular patches of fibrous tissue. Two irregular fibrotic areas, firm and brownish yellow, appeared to be infarcts. On cut section the splenic substance was uniformly dark reddish gray. Malpighian elements and trabeculations were not conspicuous. The pulp was firm and did not scrape away. The consistency was rubbery resilient. The splenic artery and vein were normal in appearance.

Microscopically the conspicuous features were the uniform dilated sinusoids containing scattered monocytes, large histiocytes and occasional polymorphonuclear leukocytes The sinusoids, however, were relatively empty, their walls being lined with elongated or flattened cells. The intervening pulp spaces were quite cellular, with a predominance of monocytes, a few plasma cells and occasional polymorphonuclear leukocytes. Trabeculations were not increased and there was little, if any, excess fibrous tissue. Malpighian elements were of the usual size and architectural configuration.

The small infarcted areas showed various stages of organization, characterized by the presence of amorphous material containing cellular débris, poorly stained cells and polymorphonuclear infiltration. Throughout the more fibrous portions of the infarct were noted brown pigmented monocytes, lymphocytes, plasma cells, scattered histiocytes and large, pale, clear foam cells.

Giemsa stain of the formaldehyde fixed material and Wright's stain of impression smears showed many Leishman-Donovan bodies within the large monocytes (fig. 3).

Histopathologic studies of the lymph nodes found at the hilus of the spleen were not remarkable except that Leishman-Donovan bodies were observed in many monocytes and reticuloendothelial cells.

On December 16 the patient was given 4 cc. of a 1 per cent solution of antimony and potassium tartrate intravenously, on the 18th 3 cc. of a 2 per cent solution and on the 20th 4 cc. of a 2 per cent solution. On December 21 he was given 0.2 Gm. of neostibosan intravenously and then 0.3 Gm. daily until the 27th. From that date he was given 0.3 Gm. every other day

Fig. 2.—Enlarged spleen, weighing 1,770 Gm.

until a total dosage of 4.7 Gm. of the drug had been administered. The patient's improvement was quite noticeable shortly after the institution of neostibosan therapy and was characterized clinically by an augmented appetite, normal temperature, gradual gain in weight and increase in sense of well-being. He was ambulant ten days postoperatively. The blood picture reached a stationary level with hemoglobin 90 per cent (14 Gm.), 4,500,000 red blood cells per cubic millimeter, 9,400 leukocytes per cubic millimeter, 50 per cent mature polymorphonuclear leukocytes and 2 per cent juvenile forms, 4 per cent eosinophils, 42 per cent lymphocytes and 2 per cent monocytes. By January 1945 the platelet count had risen to 150,000, the reticulocyte count was 1.1 per cent, clotting time was four minutes five seconds, bleeding time was three minutes fifty-five seconds, pro-

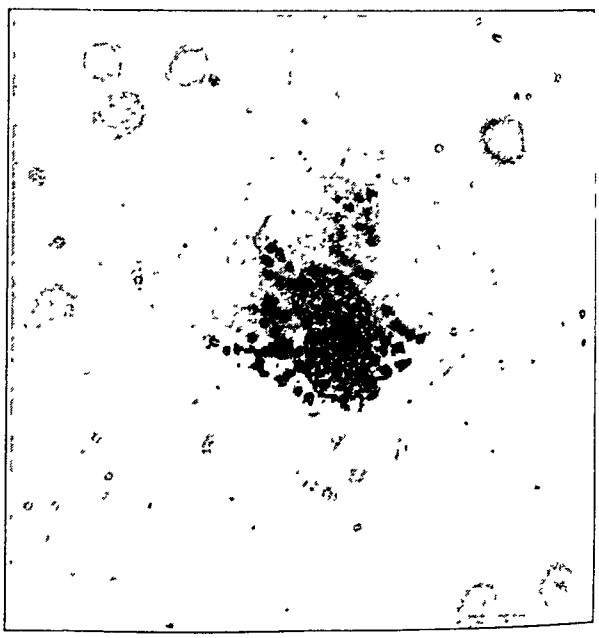

Fig. 3.—Leishman Donovan bodies within enlarged monocyte.

thrombin time was 95 per cent of normal control, hematocrit was 45 per cent and the sedimentation rate was 94 mm.

Numerous blood smears for Leishman-Donovan bodies were negative. The formol-gel test, which was strongly positive at first, gradually became less so, and at the time of this writing it is only faintly positive. The plasma proteins were 7.8 Gm. per hundred cubic centimeters, albumin 1.6 Gm. per hundred cubic centimeters, globulin 6.2 Gm. per hundred cubic centimeters and the albumin-globulin ratio 0.2. Urinary examination was negative except for a faint trace of albumin

SUMMARY

Kala-azar simulating splenic anemia was found in a 22 year old Italian enlisted man, who in all probability contracted the disease in Sicily. Following a presumptive latent period of two years the disease appeared with manifestations resembling an acute surgical condition of the abdomen.[3] Splenectomy was performed because of the patient's very poor progress and apparently hopeless prognosis, the mechanical abdominal discomfort, the undetermined cause of the splenomegaly and finally its possible therapeutic value. Histopathologic studies of the spleen showed the presence of Leishman-Donovan bodies, which were not found preoperatively in numerous examinations of the circulating blood and bone marrow. The patient's postoperative course was uneventful and apparent recovery has been accomplished by the administration of neostibosan.

ADDENDUM

Since this article was submitted, the Army Medical Museum has reported that Leishman-Donovan bodies were found in the button bone biopsy which was done during the diagnostic course. It is stated, however, that their identity would have been questionable without the knowledge of the fact that the patient had kala-azar. But they were present in the bone. Also in *War Medicine*, March 1945, there have been reported by Captains Joseph H. Burchenal, M. C., and Robert P. Woods, M. C., 3 cases of kala-azar in American troops returning from overseas, which serves to accentuate the warning as expressed in this report.

AMERICAN HEALTH RESORTS

THE PLACE OF SPA THERAPY IN THE TREATMENT OF CARDIOVASCULAR CONDITIONS

CARL R. COMSTOCK, M.D.
SARATOGA SPRINGS, N. Y.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

"Though chronic disease frequently remains with the patient, its proper management and treatment often controls and nearly always slows the progress of the disease, and such treatment teaches the patient to accommodate himself to his physical limitations and to live a useful and happy existence without further injury. It also teaches him to increase the reserve of the handicapped functions. It makes clear to the patient the wisdom of utilizing fully such functions as have little or no handicap and reeducates him to get joy out of doing things which he can do rather than insisting on doing the things which he cannot do." [1]

The problem of cardiovascular disease is the largest in size in the field of chronic disease.[2] Vital statistics show that it leads all other causes of death in those over 45 years of age. The studies of the American Heart Association indicate that between 1.5 and 2 per cent of the population of this country are afflicted with it in one form or another. In the attempt to ameliorate this situation there have been established a few private and public facilities organized as sanatoriums or as spas. My purpose in this paper is to create a clearer concept of what a spa as conducted in this country consists, how it functions, and what its relationships and availability are to the practitioner at large.

The physical components of a spa which concerns itself largely with cardiovascular disease are presumably well known to all physicians, but it might be well to visualize in a few words the essentials: reasonably level, pleasant, spacious and partly wooded terrain, of not too great altitude and with a climate which for the greater part of the year is equable and moderate as to heat, cold and humidity, accommodations for the varying social economic levels—accommodations which specialize in the particular needs of the patient; facilities for physical therapy; suitable amusements and relaxations. The concept should be one of pleasant and peaceful surroundings with the tempo of life slowed.

With these tools at hand it is the purpose of the spa physician to establish a maximum of cardiac reserve and to teach the patient to live within his individual capacity. The opportunity created during a period of several weeks is exceptional in that the patient is seen daily and at some length. The physician learns in detail not only the physical but the emotional status of his patient and of almost equal importance the impact of his environment. An understanding of these factors points the way toward the solution of the problem as far as it can be solved.

It would perhaps be pertinent to emphasize the wisdom on the part of the home physician in forwarding to the spa physician a summary of the case history with progress together with essential laboratory data, since the spa physician is attempting to carry on in perhaps greater detail and with more leisure the ideas and wishes of the home physician. A mutual understanding of what is to be undertaken is highly essential. This, however, does not preclude the necessity of a competent examination on the part of the spa physician, since it is more than a little difficult to get an adequate picture of the myocardial status from letters and laboratory reports, and the success of a regimen depends particularly on a careful estimate of what the individual heart is capable and a goodly amount of supervision in the doing of it. Many changes and adjustments in detail take place during the program.

Conceivably some misunderstanding might exist concerning the types of patient to whom the spa regimen is suited, and a word in the matter would seem warranted. He is ambulatory. He may have a mild degree of congestive failure but no more, or a moderate degree of coronary failure. Often he is in that phase of convalescence between the end of hospitalization and the return to routine. Frequently he has suffered a mild to moderate damage from coronary thrombosis. More often he is represented by the patient suffering from a coronary insufficiency gradually increasing through the years and who returns annually for a period of self discipline and reconditioning. A lesser number constitute the group afflicted by quiescent and compensated rheumatic heart disease, but by far the largest group suffer with hypertensive disease with varying degrees of myocardial damage.

Experience has shown that patients with syphilitic heart disease do not do well, nor patients who are prone to frequent attacks, though often mild, of edema of the lungs.

It is more than likely that the physician referring a patient to a spa would for his own knowledge and for the sake of advice to his patient wish to have some concept of what constitutes a spa regimen. The general plan of treatment entails a fairly thorough organization of the patient's day and has to do largely with rest, exercise, diet and the teaching of a calm, philosophic outlook on life in general and on the cardiovascular handicap in particular. Also it has to do with the matter of a mineral bath, the essence of which is carbon dioxide, an agent of considerable potency as a cardiac and respiratory stimulant and as a vasodilator.

One considers the matter of rest first because it plays so large a part in the restoration of cardiac competence and in the retardation of the progress of cardiovascular disease. It conceives not only of physical rest but also of that state of emotional equilibrium which is well expressed by the term "calm philosophy of life." It implies a controlled emotional state that permits true relaxation. It necessitates freedom from problems to be solved and from moral obligations to be met. It implies also suitable recreation.

The amount of physical rest needed can be determined best by the status of the myocardium and its response to effort. It falls naturally into periods following major meals and varies in amount with the individual. One or two hours after luncheon are particularly indicated

1. Wyckoff, John (dean of the Medical College, New York University): Address delivered at laying of the cornerstone of the Simon Baruch Research Institute at Saratoga Spa published by the state of New York, Saratoga Springs Authority.
2. National Health Survey (1935-1936) conducted by the National Institute of Health, U. S. Public Health Service

and often a half hour before dinner is advisable. A quiet period after the evening meal is essential, though it need not necessarily imply bed rest. Games which tend to excite or create problems are inadvisable during this period, since often they are conducive to poor sleep. Reading which can be given up easily and the enjoyment of music are most satisfactory. Eight to nine hours of sleep are desirable, and breakfast in bed is not only pleasant but frequently indicated. Often one day a week in bed is an excellent investment of time.

EXERCISE

About twenty years ago Sir James Mackenzie,[3] in speaking of exercise in heart disease, postulated that "the guide in these persons is the patient's response to effort. It may be taken for granted that effort which he performs with comfort is not harmful but beneficial, in the sense that exercise of the heart muscle within the limits of its power keeps the muscle in good condition." More recently White,[4] in his experience, states that "it is important generally to allow a patient with heart disease to take as much exercise as he reasonably and safely can, with periods of rest, perhaps of a few days each, because it is physical exercise that helps to maintain a state of general good health, and undoubtedly the proper functioning of the peripheral circulation resulting from reasonable exercise aids the heart in its work. The most practicable exercise is walking and this is also quite uniformly good; it can be graded easily by three factors—distance, speed and grade (hill climbing)." Nylin,[5] in a paper on physical exercise in cardiac conditions, has put the matter of exercise in a most satisfactory manner. He states that "best results are obtained where there is a correct proportion between the demand of the exercise on the heart and the degree of cardiac reserve power." It is acceptable, then, that the cardiovascular system is benefited by that amount of exercise which it can undertake without embarrassment, for it is altogether conceivable that the myocardium will find itself in the same status as the general musculature.

The exercise which may be prescribed by the spa physician will fall under two types—active or passive—and depends on the status of the individual myocardium. Although difficult to demonstrate by controlled experiment, it is generally accepted that active or voluntary exercise is of more benefit than is any passive or involuntary form and is the type of choice when circumstance permits. Of all forms of active exercise walking, as has been stated by White, lends itself most easily to graded work. Golf on level and short courses often gives point and pleasure to the treatment, as do other suitable forms of recreational activity such as croquet. Passive exercise is most often applied as massage, frequently combined with passive movements of flexion, extension, rotation and circumduction of the limbs.

DIET

It is desirable to eliminate the unnecessary burden of obesity to the degree to which reduction is consonant with the safety of the individual. The stay at a spa creates an excellent opportunity to effect this when indicated, which is rather frequently. In any event simple foods, properly prepared and in moderate amount, are a basic part of the regimen. Ample provision is made for special types of diet as required when the complication of diabetes or gout exists for instance. By and large the tendency is to restrict fluids to 3 or 4 pints daily and to keep salt moderately low.

THE CARBON DIOXIDE BATH

The physiologic effect of the carbon dioxide bath has been studied extensively during the past twenty years and considerable information on the response of the body to it has been accumulated. Professor Franz M. Groedel[6] has reviewed the subject recently, and studies by Dr. Walter S. McClellan[7] at the Saratoga Spa have summarized our limited knowledge: "The physiological observations of the influence of the CO_2 baths show a decrease in the pulse rate and increase in the pulse pressure dependent mainly on a drop of the diastolic pressure, a better emptying of the venous blood vessels, a hyperemia with increased capillary circulation, a slightly elevated minute volume output of the heart, an increase in respiration and elimination of large quantities of the CO_2 through the lungs." Claims beyond these cannot be accepted as conclusive until research now in progress has clarified and substantiated them.

A rare opportunity to teach a suitable conduct of life for the individual is present during the stay at a spa, for by the end of several weeks' observation of response to the regimen, and especially to effort the physician there should have fairly concrete data on which to advise the patient. Education concerning the "red flags" is particularly indicated, and of these that of a sense of exhaustion is emphasized particularly. Shortness of breath or precordial distress is less often passed over lightly by the patient. Emotional stability is stressed. A sense of humor, a calm and somewhat fatalistic philosophy and emphasis on the things which the patient can do, rather than on those he cannot—all of these are much dwelt upon. He is urged to keep as physically fit as his capacity permits. By learning his problem and facing it squarely he gains not only the conquest of fear but a way of life.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., *Secretary.*

DANGERS FROM THE EXTERNAL USE OF SULFONAMIDES

Frequent mention has been made of the dangers from the external use of the sulfonamides. Almost two years ago the Council adopted for publication (THE JOURNAL, Oct. 16, 1943, p. 411) a statement reviewing the status of the local use of the sulfonamides and warned against indiscriminate use. Since that time other warnings have appeared. Abramovitz[1] reviewed the dangers inherent in the local use of the sulfonamide compounds which apply not only to the skin but to the ear, eye, nose and even to prolonged dusting or packing in cavities. Abramovitz, however, thinks that the latter mode of administration provides fewer possibilities of later reactions.

The frequency of reactions is difficult to estimate, as probably many cases have never been reported. However, several signifi-

1. Abramovitz, E. W.: Hazards of the External Use of Sulfonamide Compounds, Arch. Dermat. & Syph. 50: 289 (Nov.) 1944.

cant studies have been made. Darke[2] reported sensitization in 5.5 per cent of 218 minor surgical patients treated with a 5 per cent sulfathiazole cream. Dermatologists are seeing many such cases, and recent conversation with an ophthalmologist revealed that an increasing number of cases of sensitivity to sulfonamides are being seen by men in that field. Downing[3] observed 300 serious cutaneous reactions where sulfonamides had been used in industrial dermatitis. J. H. Schwartz of Boston, in discussing the Abramovitz paper, reported that a man who used "nose drops" containing sulfonamides later contracted pneumonia and received sulfonamide therapy. A severe exfoliative dermatitis and anuria developed and the patient died. A member of the Council has likewise seen a death under even as bizarre conditions.

The type of cutaneous reaction varies greatly. It may be simply a local fixed reaction or there may be a generalization or an exfoliative dermatitis. The process may be further complicated because of the photosensitization that the patient develops. Relapses are not uncommon, and with scalp involvement there may be temporary loss of the hair. Most of the cases seen by dermatologists do not result from medication prescribed by the physician. Usually the patient has purchased freely a sulfonamide cream preparation for a skin disorder. Bloom[4] read a paper before the Section on Dermatology of the New York State Medical Society and introduced a resolution strongly disapproving the indiscriminate use of the sulfonamide drugs in relatively harmless disorders of the skin and recommending that the society condemn the use of prepared dressings containing sulfonamides which are sold promiscuously to the public. The Department of Health of the City of New York on Aug. 31, 1943 amended section 118 of the Sanitary Code to require a physician's prescription for sulfonamide drugs not only for internal use but for external use whether they are made available in the form of powders, ointments or sprays.

The therapeutic value of the sulfonamide compounds is well established, but they are undoubtedly often being used carelessly for skin lesions. Their use on the skin for ordinary skin disorders should be frowned on. Other measures should be employed first; then if local sulfonamide therapy is necessary it should not be continued for a period longer than five days because of the danger of sensitization of the patient. Further, such therapy should be employed only under a physician's direction.

One of the Council members who was on active service in the North African theater of operations has informed the Council concerning the strong recommendations which were issued by himself and a consulting physician against the local use of sulfonamide creams in the treatment of superficial skin infection. The recommendations were based on experience gained in this theater. The rate of sensitization from such creams appears to be far higher than that observed following the oral use of the drug. This bears special significance when it is realized that the value of such creams in superficial skin infections under ordinary conditions of use is so limited that their routine use is not warranted. According to the Council's informant, the local use of sulfonamide powders was not recommended except in perforating wounds of the abdomen. In this condition sulfanilamide is instilled in the peritoneal cavity and the procedure is considered an aid in reducing infection and a life saving measure.

Special attention should be given to the possible dangers that exist in pediatric practice, e. g. the possibility of harmful results following the routine use of suspensions of sulfonamides for the prevention of impetigo in nurseries.

There are real dangers from the external use of the sulfonamides, and such use should be limited to a comparatively few skin disorders which may be effectively treated by a sulfonamide preparation. Only a physician can determine the condition most likely to respond, and even he should exercise careful judgment in prescribing and using a sulfonamide ointment, emulsion or other preparation. Claims supporting their value in "nose drops" and other similarly exploited preparations remain to be generally supported. Certainly there does not seem to be sufficient evidence to justify over the counter sale of any sulfonamide preparation, while on the other hand there is adequate evidence concerning the dangers of promiscuous use.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., *Secretary.*

PREPARATIONS USED IN THE FEEDING OF INFANTS (*See* Accepted Foods, 1939, p. 156)

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT JUNIOR FOODS CHICKEN SOUP WITH VEGETABLES, consists of chicken broth, water, farina, carrots, celery, chicken meat, salt, onion and yeast.

Analysis (submitted by manufacturer).—Total solids 12.30%, moisture (by difference) 87.70%, ash 1.39%, fat (ether extract) 1.72%, protein (N × 6.25) 3.15%, crude fiber 0.59%, carbohydrates other than crude fiber (by difference) 5.45%, calcium (as Ca) 0.019%, phosphorus (as P) 0.027%, iron total 0.49 mg. per hundred grams, iron "available" (bipyridyl method) 0.38 mg. per hundred grams, copper (McFarlane method) 0.06 mg. per hundred grams.

Calories.—14 per ounce; 50 per hundred grams.

Vitamins.—

Vitamin A equivalent	640 U. S. P. units per hundred grams
Thiamine	0.035 mg. per hundred grams
Ascorbic acid	0.8 mg. per hundred grams
Riboflavin	0.038 mg. per hundred grams
Niacin	0.45 mg. per hundred grams

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT STRAINED CHICKEN SOUP WITH VEGETABLES, consists of chicken broth, water, farina, carrots, celery, chicken meat, salt, onion and yeast.

Analysis (submitted by manufacturer).—Total solids 10.42%, moisture (by difference) 89.58%, ash 1.49%, fat (ether extract) 1.35%, protein (N × 6.25) 1.91%, crude fiber 0.17%, carbohydrates other than crude fiber (by difference) 5.50%, calcium (as Ca) 0.036%, phosphorus (as P) 0.016%, iron total 0.69 mg. per hundred grams, iron "available" (bipyridyl method) 0.62 mg. per hundred grams, copper (McFarlane method) 0.17 mg. per hundred grams.

Calories.—11.9 per ounce; 42 per hundred grams.

Vitamins.—

Vitamin A equivalent	500 U. S. P. units per hundred grams
Thiamine	0.042 mg. per hundred grams
Riboflavin	0.050 mg. per hundred grams
Niacin	0.57 mg. per hundred grams

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT STRAINED PUMPKIN.

Analysis (submitted by manufacturer).—Total solids 7.06%, moisture (by difference) 92.94%, ash 1.23%, fat (ether extract) 0.37%, protein (N × 6.25) 0.45%, crude fiber 0.70%, carbohydrates other than crude fiber (by difference) 4.31%, calcium (as Ca) 0.047%, phosphorus (as P) 0.016%, iron total 0.35 mg. per hundred grams, iron "available" (bipyridyl method) 0.23 mg. per hundred grams, copper (McFarlane method) 0.06 mg. per hundred grams.

Calories.—6.2 per ounce; 22 per hundred grams.

Vitamins.—

Vitamin A equivalent	2,530 U. S. P. units per hundred grams
Thiamine	0.013 mg. per hundred grams
Ascorbic acid	2.8 mg. per hundred grams
Riboflavin	0.045 mg. per hundred grams
Niacin	0.51 mg. per hundred grams

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT STRAINED PUMPKIN AND SQUASH, consists of pumpkin and squash.

Analysis (submitted by manufacturer).—Total solids 6.81%, moisture (by difference) 93.19%, ash 1.10%, fat (ether extract) 0.58%, protein (N × 6.25) 0.45%, crude fiber 0.62%, carbohydrates other than crude fiber (by difference) 4.06%, calcium (as Ca) 0.050%, phosphorus (as P) 0.012%, iron total 0.44 mg. per hundred grams, iron "available" (bipyridyl method) 0.35 mg. per hundred grams, copper (McFarlane method) 0.06 mg. per hundred grams.

Calories.—6.5 per ounce; 23 per hundred grams.

Vitamins.—

Vitamin A equivalent	1,850 U. S. P. units per hundred grams
Thiamine	0.012 mg. per hundred grams
Ascorbic acid	3.7 mg. per hundred grams
Riboflavin	0.046 mg. per hundred grams
Niacin	0.53 mg. per hundred grams

SATURDAY, AUGUST 4 1945

DENGUE VACCINE

Thanks to the heroic cooperation of inmates of the New Jersey State Prison, who volunteered without offer of reward to serve as subjects for numerous inoculations with virus, Sabin and his associates [1] of the Army Epidemiological Board announce the development of a promising new vaccine for dengue fever

In 1928 Manoussakis [2] found that dengue virus (infective human serum) which had lost its pathogenicity as a result of irradiation heating or prolonged storage would not protect nonimmune human beings against subsequent inoculation with fully virulent dengue virus He concluded that inoculation with a nonviable dengue vaccine was without promise as a prophylactic measure Blanc and his associates [3] of the Hellenic Pasteur Institute subsequently found that repeated vaccination with a dengue vaccine (infectious serum) attenuated by the addition of 5 to 8 per cent bile confers an effective immunity The virus-bile mixture, however, lost all traces of its immunizing power within fifteen minutes after preparation Such an unstable vaccine was of little practical promise Equally unsuccessful attempts to prepare an attenuated vaccine were made with individual bile salts, formaldehyde, chloroform, phenol and other chemical agents

These earlier failures narrowed the search for a practical dengue vaccine to the possibility of developing a natural human virus of sufficiently low virulence or an antigenically similar virus from lower animals Evidence was not available, however, that any wild or domestic animal contracts dengue naturally during an epidemic, in spite of the probability that many are bitten by infective mosquitoes Attempted experimental inoculation of domestic animals also gave negative results Guinea pigs inoculated intraperitoneally with massive doses of infected human blood may at times harbor the virus for as long as nine days without febrile response or other evidence of illness Inoculation from these animals into other guinea pigs, however, failed to show a continuation of the cryptic infection

In 1931 Dinger [4] attempted without success to propagate the dengue virus by intracerebral inoculation into young mice, using infective human serum as the inoculum In the New Jersey prison experiments this technic was varied by inoculating young mice intracerebrally with an ultracentrifuged concentrate of such serum, this concentrate containing approximately 10 million minimum human infective doses per cubic centimeter On the first attempts only 10 to 20 per cent of the inoculated Swiss mice exhibited clinical signs of infection and then only after an incubation period of nearly four weeks

Serial passage was accompanied from these few first generation mice, 0 2 cc of a 5 per cent centrifuged suspension of brain and cord being used as the inoculum As a result of murine serial passage there was a definite increase in the virulence for mice of the dengue virus By the sixth passage the incubation period had been reduced to two weeks, and the incidence of fatal paralysis increased to approximately 60 per cent By the ninth passage the fatalities were still further increased to 90 per cent and by the fifteenth passage to 100 per cent

The virus, however, did not acquire a pathogenicity for cotton rats, guinea pigs, hamsters or rabbits Its human pathogenicity was greatly reduced Up to the fifth passage 0 2 cc. of a 1 1,000 dilution of centrifuged mouse brain and cord suspension produced skin lesions at the site of intracutaneous injection in human volunteers This was followed six to nine days later by fever, maculopapular and petechial rash leukopenia and enlargement of certain lymph nodes Infective concentrations of the virus were demonstrable in the blood of the inoculated volunteers, and transmission by Aedes aegypti mosquitoes was accomplished A solid convalescent immunity to subsequent infection with fully virulent dengue virus invariably followed this inoculation

By the tenth passage subcutaneous injection of fifty times this routine dose usually gave rise to no systemic reactions in the human volunteers, there being at most only a slight fever without headache or malaise lasting less than twenty-four hours When the same multiple dose was given simultaneously or mixed with the regular U S Army dose of yellow fever vaccine, even these occasional symptoms were rarely noted, presumably because of the well known "interference phenomenon" between heterologous viruses All human volunteers inoculated with the practically avirulent tenth mouse passage dengue virus acquired a solid immunity against

subsequent inoculation with fully virulent virus or to bites of mosquitoes from a batch of mosquitoes demonstrably infective to nonimmune human volunteers. Volunteers immunized with the combined dengue-yellow fever vaccine also developed neutralizing antibodies for the yellow fever virus.

From these preliminary successes Sabin concludes that mouse adapted dengue virus could be used safely and effectively as a prophylactic vaccine against dengue fever. Whether or not a polyvalent vaccine would be required has not yet been determined. If this murinized dengue vaccine proves clinically successful, the War Department would be fully justified in awarding suitable recognition to each inmate of the New Jersey State Prison who volunteered for the experimentation.

MUSCLE SPASM IN POLIOMYELITIS

Still in the field of controversy is the concept that spasm in the antagonists of muscles weakened by poliomyelitis is the damaging symptom. The use of the Kenny technic for combating this symptom relieves pain and stiffness. Many observers have reported that this method minimizes deformities and the degree of paralysis. These observations have tended to discourage passive splinting and to promote active treatment in the acute stage of the disease.

Muscle spasm can be studied by physical methods in which the personal or subjective element is largely eliminated. Extremely minor contractions of muscle in situ can be recorded by action currents. A particular pattern of action current records is established as definite evidence of muscle spasm. For purposes of recording, spasticity in a muscle can be evoked by a sudden stretching of the muscle. Schwartz and Bouman [1] made oscillographic records of muscle action in 7 cases of poliomyelitis, in 3 with spastic paralysis and in 3 normal subjects. In poliomyelitis, spasticity of the muscles was found not only in the antagonist of the weakened muscle but also in the weakened muscle itself and in muscles in parts of the body in which clinical symptoms of the disease are not evident. They concluded that the spasticity is reflex and is not present in the completely paralyzed muscle. The investigators were not able to say whether the spasticity is actually responsible for weakening of the muscle or whether it is a phenomenon which is merely another consequence of the disease.

Watkins, Brazier and Schwab,[2] in their electromyographic studies of 11 cases of poliomyelitis over a period of two years, found that the term "muscle spasm" is inadequate to describe the complexity of this condition, which is revealed by electromyography. In the acute stage only muscles with some degree of paralysis discharge electrical potentials at rest; these electrical abnormalities are not correlated with the presence of clinical "spasm." They state further that the concept of "mental alienation" did not contribute to the explanation of paresis in their cases, since objective signs of a disease process were always present in the paretic antagonists of muscles in "spasm." They conclude that the only one of the three concepts of Kenny upheld by their objective measurements is that of "incoordination," although the term is misleading. They have demonstrated not only simultaneous activation of protagonists and antagonists but also intermittent synchrony of individual discharges from opposing muscles, such as is found in peripheral nerve injuries during regeneration of axons. They believe that the term "disordered reciprocal innervation" is a more descriptive term for this type of dysfunction.

A more recent study by Watkins and Brazier [3] was concerned with the effect of various forms of thermal therapy and of neostigmine on muscle spasm as recorded by the standardized electromyographic method. These investigators studied the effect of a single application of a therapeutic agent on muscle spasm during the first weeks of the disease. The degree of spasm was measured by the voltage of the electrical potentials discharged by the muscles on passive stretching. On each test day a number of control observations were made on every muscle before the therapeutic procedures were begun. The methods investigated were twenty minute applications of the Kenny type of hot packs, infra-red irradiation, luminous heat, short wave diathermy by induction technic and intramuscular injection of 1.6 mg. of neostigmine methylsulfate. They found that single application of hot packs, infra-red irradiation and diathermy were without effect on the muscle spasm. Luminous heat and neostigmine caused a decrease in spasm of approximately 25 per cent. This degree of change was not great enough to indicate a specific effect on spasm. Further studies on repeated use of a single method of treatment will be necessary for final evaluation.

Solution of the problems presented by the symptoms of poliomyelitis will probably come through the correlation of objective investigations with clinical observations rather than from clinical observations alone. The newer mechanical methods of study emphasize the great importance of research designed to eliminate the subjective factors in evaluating symptoms or their relief.

Current Comment

HOSPITAL PROGRESS ANNIVERSARY

With a silver cover *Hospital Progress,* the official journal of the Catholic Hospital Association of the United States and Canada, celebrates a silver jubilee in May 1945. Conspicuous is the high tribute paid by many leaders in the medical and hospital fields. During the twenty-five years celebrated by this publication the growth and development of the Catholic hospitals, the quality of the service that they render, the spiritual ideals that they foster in the maintenance of health and medical care, have been an inspiration to every one in the field of medicine. All who are familiar with the nature of man and with a knowledge of disease recognize the important part played by the environment and by personal contacts in the rendering of care to the ailing human being. The loss of this important factor for recovery would be a disaster to medical science. Many of the articles in this issue of *Hospital Progress* are a pledge for the continuous maintenance of the self-sacrificing personal and spiritual service given by these institutions not only to the people of Catholic faith but to all the people of the United States. Especially noteworthy also in this large special issue is the cleanliness of the medical advertising—free from the advertisements of nostrums, bogus devices or any of the other forms of charlatanism that still pervade the pages of some publications in the field of medicine. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, soon to celebrate the one hundredth anniversary of the American Medical Association, congratulates a contemporary on twenty-five years of which it may well be proud.

THE MATERNAL AND CHILD WELFARE ACT OF 1945

Senator Pepper of Florida on July 26, for himself and nine other members of the Senate Committee on Education and Labor, introduced S. 1318 to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children and for other purposes. Joining Senator Pepper in sponsoring this legislation were Senator Walsh of Massachusetts, Senator Thomas of Utah, Senator Hill of Alabama, Senator Chavez of New Mexico, Senator Tunnell of Delaware, Senator Guffey of Pennsylvania, Senator LaFollette of Wisconsin, Senator Aiken of Vermont and Senator Morse of Oregon. The bill was referred to the Senate Committee on Education and Labor. It will authorize an appropriation of $100,000,000 for the fiscal year ending June 30, 1946: $50,000,000 for maternal and child health services, $25,000,000 for services for crippled children, $20,000,000 for child welfare services and $5,000,000 for expenses necessary to enable the Children's Bureau to administer the provisions of the bill. Thereafter such sums will be made available as the Congress shall decide. Apparently any person under 21 years of age is to be considered a child within the meaning of the provisions of this bill, with respect both to the contemplated program for maternal and child health services and to the contemplated program for crippled children. Services will be made available to all who elect to participate in such a program, irrespective of financial status, race, creed, color or national origin. Beneficiaries will be permitted to select the physician, hospital, clinic or health agency of choice from among those that meet prescribed standards. The bill provides that the physician, hospital, clinic or health service agency selected may refuse to accept the case. If the beneficiary does not exercise his right to make a selection, the state plan must set forth the method by which care will be made available. Payments to individual physicians will be on a "per capita, salary, per case or per session basis" or, in the case of consultations or emergency visits, on a fee-for-service basis. A state plan must provide for a general advisory council and for technical advisory committees. On a federal level there will also be advisory committees with which the Children's Bureau will be required to "consult." This would seem to be an effort to extend and expand the EMIC program after the termination of the war. A detailed analysis of the provisions of the bill will be published in an early issue of THE JOURNAL.

CALCIUM CONTENT OF TISSUES

Administration of the relatively insoluble drugs such as sulfaguanidine and succinylsulfathiazole reduces the synthesis of various vitamins and possibly amino acids by the intestinal bacteria. Pilgrim and Elvehjem [1] have recently demonstrated that the feeding of succinylsulfathiazole to rats is followed by an accumulation of calcium in the livers of the animals that receive the drug for two to twelve weeks. Since microscopic studies indicated that there was not an increased deposition of inorganic calcium salts, the increased calcium could not be due to calcification following necrosis. Livers of rats with the increased calcium content showed in addition approximately 50 per cent increase in weight over those of the control animals, an observation which had been made earlier in animals receiving various sulfonamides. The administration of a solubilized liver concentrate for ten to forty days along with the sulfonamide reduced the high calcium content of the livers but did not reduce the calcium content of normal livers. In the case of sulfadiazine there may be an increased calcium content of the kidney, but this is believed to be due to the deposition of the insoluble acetyl derivative of the drug, which causes irritation and resulting calcification. The high calcium content of the liver is not believed to be caused by a similar mechanism but thought to be primarily a metabolic defect, since the sulfonamide which produced this condition most consistently was succinylsulfathiazole, the least readily absorbed of drugs of the sulfonamide type. Furthermore, the changes can be remedied by feeding a liver concentrate which is known to be rich in nutritional factors.

MEDICINE AND THE WAR

ARMY

ARMY NOW RELEASING MEDICAL OFFICERS

Approximately 900 medical corps officers have been relieved from the Army since Jan. 1, 1945 and approximately 7,000 more will be released during the next nine months, the War Department recently announced. One thousand medical corps officers have been requisitioned from Europe for return to the United States during June and July to relieve a shortage of doctors in the army hospitals in this country, to relieve doctors who have not had overseas service and to increase the rate of the return of doctors to civilian practice. During the past six months the patient load in army hospitals in the United States has doubled.

There will be an initial lag in the discharge of medical officers over other officers because sick and wounded soldiers remain in hospitals long after battles are over. Provision is made, however, for their release as soon as possible. The peak load of patients in army general and convalescent hospitals in the United States is not expected to be reached before late this fall, assuming that the present casualty rate in the Pacific continues.

The plans to discharge medical officers will take into consideration such factors as requirements of the service and of civilian population, adjusted service ratings of the individual officers and their own desires for release or retention.

The redeployment of medical officers from Europe to the Pacific for relief and return of doctors in that theater, although being expedited, is still a time consuming operation and must necessarily be geared with the entire redeployment and readjustment program. For example, the medical officers now in Europe who are available and eligible for return to the United States must be given leave and must be assigned to stations here, redeployed or discharged. Medical officers in the Pacific cannot be returned until replacements are available.

DISCHARGE OF MEDICAL OFFICERS OF THE ARMY

The Office of the Surgeon General of the Army expects to announce next week a detailed statement of the policy that will prevail regarding the discharge of medical officers. An adjusted service point system is being established which will guide the determination. It is understood that the age, the nature of the service rendered, the extent of service abroad and similar factors will be taken into account. A statement in TIME magazine to the effect that "Army doctors with little or no prospect of being mustered out were those already in the Pacific area (especially men in some much needed specialty like psychiatry") is said by the Office of the Surgeon General to be absolutely without any foundation in fact.

MEDICAL PERSONNEL ENTER STALAG VI

The 515th Medical Clearing Company, under the command of Major Henry L. Harrell, and two officers and eighteen enlisted men from the 118th evacuation hospital were the first medical personnel to enter Stalag Vi, at Hemer, Germany. Over 20,000 prisoners, all undernourished, and 4,000 patients in the Stalag Hospital were found. There were no sanitary facilities, tuberculosis was rampant and there were many cases of typhus. All prisoners were infested with lice. A sanitary detail, a delousing detail and other details necessary for establishing order from chaos were immediately organized. All of the 20,000 prisoners were deloused by the men of these medical units, using DDT powder. Two new hospitals were organized and staffed with personnel from the 515th Clearing Company. Eight other hospitals with German patients were supervised by officers and men from the company. The three medical administrative officers of the company were responsible for the records and supplies for all these hospitals.

TRANSPORTATION OF WOUNDED

The War Department recently announced that well over a million trips involving multimillions of miles had been made by some 510,000 wounded or sick soldiers between November 1942 and June 30, 1945. Of the 510,000 patients approximately 81,000 were flown to inland hospitals by the Air Transport Command from airports of debarkation. Of the more than 426,000 patients returned by ship, about 346,000 came by transport and nearly 81,000 by the Transportation Corps' twenty-three U. S. Army hospital ships and three other hospital ships operated by the Navy for the Army. Another 84,000 were returned by air. During the first six months of 1945 the army used 251 army owned hospital cars, making them do the work of 3,804 Pullmans which otherwise would have had to be employed. By August it is expected to add 69 new unit-type cars to increase the fleet to 320. In addition to these, the Army has 60 medical kitchen cars which are used on long hospital train movements.

Major Gen. C. P. Gross, chief of transportation, Army Service Forces, stated that the army's hospital cars were not enough to handle all patients and, consequently, for the first six months of this year alone the Army was forced to enlist the aid of the railroads in obtaining 5,978 Pullmans, 884 of them for use in June.

While being carried by rail, patients are cared for by a staff of doctors, nurses and medical technicians trained by the Office of the Surgeon General and made available to the various service commands. "Convoy personnel" of this type is made available for moves of from 1 patient to a hospital train of patients. The volume of convoy personnel for the first six months of this year was 54,663, of which 10,235 were for June alone.

General Gross said that by August all transportable patients should have been returned to the United States from England.

ARMY AWARDS AND COMMENDATIONS

Major Carl T. Javert

The Soldier's Medal was recently awarded to Major Carl T. Javert, formerly of New York. The citation read "for heroism at great risk of life in Italy. On April 9, 1945 an ammunition ship loaded with aerial bombs exploded in a harbor in Italy, and Major Javert immediately rushed to the scene. Heedless of great danger, he set upon the dangerous and extremely difficult task of rendering first aid and extricating wounded personnel from the demolished buildings about the perimeter of the explosion. In one instance, using an improvised crow bar and sledge hammer, he extricated a seaman from beneath a heavy locker and heavy beams of masonry. Several others were likewise extricated and removed and their lives saved, despite a raging warehouse fire which set off repeated hails of small arms ammunition which flew about the scene of rescue. Minor explosions also rocked the partly demolished building, causing

showers of débris and masonry to fall about him. By his outstanding leadership, humanity, courage and devotion to duty, despite grave hazards and multiple threats to his safety, Major Javert reflects great credit on himself and on the armed forces of the United States of America." Dr. Javert graduated from the University of Buffalo School of Medicine in 1932 and entered the service Aug. 19, 1942.

Colonel Bradley L. Coley

The Legion of Merit was recently awarded to Col. Bradley L. Coley, formerly of New York. According to the citation "He performed outstanding services as surgical consultant of the Eighth Service Command from July 1942 to February 1945. He assisted in organizing the surgical service of one hundred and five hospitals, choosing personnel with unusual keenness and assigning them to positions where their talents were used with maximum effectiveness. He overcame handicaps coincident with establishing medical installations and built the command's surgical service to a high level of efficiency, starting with meager facilities and limited personnel. With unusual ability and resourcefulness he dealt with other branches of the Army. He tirelessly devoted his great knowledge of surgery to providing exceptional surgical care for troops in the command and to preparing many highly trained surgical officers for duty in theaters of operations. By his unfailing tact, judgment and administrative skill he was in great measure responsible for the excellent record made on the surgical service of the Eighth Service Command." Dr. Coley graduated from Columbia University College of Physicians and Surgeons, New York, in 1919 and entered the service June 1, 1942.

Major John C. Angley

The Bronze Star was recently awarded to Major John C. Angley, formerly of Bryantville, Mass., for "meritorious service in support of combat operations during the period April 1, 1944 to Nov. 15, 1944 in Italy, Corsica and Sardinia. During this period Major Angley supervised malaria control activities for the army air forces and in this vital mission noteworthy success was achieved. This was due largely to his unceasing efforts and conscientious attention to the most minor details. It was imperative that the incidence of malaria and other insect borne diseases be held to an absolute minimum in units of the Twelfth Air Force to insure successful support in the invasion of southern France. These units, along with units of the Fifteenth Air Force, were stationed in some of the most highly malarious areas in the world, and the coordination, education and labor instigated and carried out by Major Angley required exceptional professional and executive abilities, plus the willingness to work many long hours. These qualities were responsible for holding malaria to an almost irreducible minimum in air force units and has been a very significant factor in the successful conclusion of air force operations for the period." Dr. Angley graduated from Harvard Medical School, Boston, in 1932 and entered the service Sept. 17, 1942.

Lieutenant Colonel Ralph S. Muckenfuss

The Legion of Merit was recently awarded to Lieut. Col. Ralph S. Muckenfuss, formerly of New York, "for exceptionally meritorious conduct in the performance of outstanding services as commanding officer, 1st Medical General Laboratory, from June 28, 1943 to Jan. 19, 1945. Through the initiative and energy of Lieutenant Colonel Muckenfuss, the 1st Medical General Laboratory, the first organization of its type, was set up in the United Kingdom. The unit performed in a superior manner its mission of assisting all hospital laboratories, performing laboratory examinations beyond the resources of hospitals, maintaining the only virus diagnostic laboratory in the United Kingdom, maintaining a veterinary laboratory and investigating the causative factors of epidemics. As United Kingdom consultant for research, Lieutenant Colonel Muckenfuss did much to further the scientific background of medical practice in the European theater of operations. Under his supervision the only blood bank in the United Kingdom was organized." Dr. Muckenfuss graduated from Emory University School of Medicine, Atlanta, Ga., in 1921 and entered the service July 22, 1942.

Lieutenant Colonel William S. Moore

The Legion of Merit was recently awarded to Lieut. Col. William S. Moore, formerly of Memphis, Tenn. The award was accompanied by a citation for "service as assistant military attaché to the legation of the United States at Cairo, Egypt, from February 1942 to February 1943. His observations and reports on military operations throughout the Middle East, particularly in the Western Desert and the El Alamein offensive, were invaluable to the War Department, especially those pertaining to the causes, treatment and evacuation of battle casualties. As military attaché and liaison officer with the representatives in Cairo of the Allied Governments in Exile from February 1943 to January 1944 he established and coordinated intelligence activities which were of great value to the headquarters of the United States Army Forces in the Middle East." Dr. Moore graduated from the University of Tennessee College of Medicine in 1938 and entered the service July 6, 1940.

Captain Philip G. Creese

The Soldier's Medal for heroism was recently awarded to Capt. Philip G. Creese, formerly of Danvers, Mass. The citation read "For heroism displayed in rescuing an enlisted man from drowning. While participating in landing exercises on a beach in England, a landing craft was swamped and a number of men were thrown into the surf. One man was carried off shore by the swell and in a few minutes was in a drowning condition. Lieutenant Creese, without hesitation, plunged into the surf and brought the drowning soldier far enough toward shore for others to assist in the rescue." Dr. Creese graduated from Harvard Medical School, Boston, in 1942 and entered the service March 13, 1943.

Major Israel Weinstein

Major Israel Weinstein, formerly of New York, was recently awarded the Purple Heart as a result of having been wounded April 25, 1945 near Regensburg, Germany, during very heavy fighting. Dr. Weinstein is division medical inspector and assistant surgeon of an infantry division. He has been on leave from the New York City Health Department, where he is assistant director of the Bureau of Health Education. Dr. Weinstein graduated from Columbia University College of Physicians and Surgeons, New York, in 1926 and entered the service Aug. 28, 1942.

Major Victor A. Bacile

Major Victor A. Bacile, formerly of Poughkeepsie, N. Y., was recently commended for "professional ability while serving with surgical units" during the heavy fighting on Okinawa. The letter of commendation pointed out that Major Bacile worked long hours day and night, without regard to his own health and safety, in caring for the wounded during the height of the bloody battle last May and praised him for his efforts. Dr. Bacile graduated from Long Island College of Medicine, Brooklyn, in 1927 and entered the service Aug. 10, 1942.

Captain George P. Schwab

The Silver Star was recently awarded to Capt. George P. Schwab, formerly of Union City, N. J., for "gallantry in action in Germany in November 1944." Dr. Schwab has also been the recipient of the Bronze Star with two oak leaf clusters "for heroic achievement in connection with military operations against the enemy" in France, Belgium and the Netherlands respectively. He graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1937 and entered the service April 10, 1941.

Major Paul A. Burgeson

The Silver Star was recently awarded to Major Paul A. Burgeson, formerly of Warsaw, N. Y., for "extraordinary gallantry in action on Aug. 2, 1944 near Coulances, France." Dr. Burgeson was also awarded the Bronze Star for meritorious service in connection with military operations against the enemy during the Normandy campaign while serving with an infantry battalion. He graduated from Cornell University Medical College, New York, in 1936 and entered the service Sept. 22, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS

Lieutenant Commander Spencer K. Phillips

The Legion of Merit was recently awarded to Lieut. Comdr. Spencer K. Phillips, formerly of Rochester, Minn. The citation accompanying the award read "For exceptionally meritorious conduct in the performance of outstanding services to the government of the United States at Tarawa, Gilbert Islands, from Nov. 20 to 24, 1943, and at Saipan and Tinian, Marianas Islands, from June 16 to Aug. 4, 1944 During the Tarawa operation he demonstrated outstanding ability as a surgeon. On the Saipan operation he came ashore under heavy enemy artillery and mortar fire on the evening of June 16. He assumed command of a medical company when his company commander became a casualty immediately after landing and by his untiring efforts and cool leadership was able to keep his men and equipment intact and at daylight proceeded to set up a hospital installation in a captured Japanese hospital building. This hospital section was the first to operate on the island and saved many lives when evacuation to ships at night could not be carried out. He later moved his company forward to a position directly in rear of the front lines, at the junction of the two main roads of evacuation, and under his cool leadership, in spite of several severe artillery barrages, his company performed invaluable service in screening casualties from all three combat regiments. His untiring devotion to duty, coolness under fire and efficient direction of his organization were an inspiration to the men under his command and in keeping with the highest traditions of the United States Naval Service." Dr. Phillips graduated from Northwestern University Medical School, Chicago, in 1940 and entered the service in January 1942.

Commander Cripps B. Shacklette

Comdr. Cripps B. Shacklette, formerly of Shively, Ky., was recently awarded the Legion of Merit "for distinguishing himself by outstanding devotion to duty during naval action in Pacific waters." The citation said that "Commander Shacklette, senior medical officer aboard an aircraft carrier, despite intensive shelling and bombing by enemy surface craft and aircraft units, remained at his post for three days and nights administering aid to the wounded and suffering" Dr. Shacklette graduated from the University of Louisville School of Medicine in 1930 and entered the service April 15, 1942.

Captain Jesse W. Miller

The following letter of commendation was recently presented to Capt. Jesse W. Miller, formerly of Washington, D. C.: "Your performance of duty while serving as executive officer of a large naval base hospital in southern England prior to, during and after the invasion of the French coast in June 1944 has been brought to my attention. You were instrumental in the successful conversion of an old British hospital to one conforming to modern hospital standards. Your assistance in the acquisition of this institution from the U. S. Army, in the maintenance of the good relations which existed with the British army, and your work in connection with the organization of the base hospital in preparation for the reception of casualties was outstanding. You exhibited, in the innumerable details of hospital administration incident to combat casualties, excellent judgment and administrative ability, thus contributing most materially to the successful work of the institution. For your initiative and outstanding service during this period you are hereby commended. This commendation carries with it the privilege of wearing the commendation ribbon." Dr. Miller graduated from the University of Nebraska College of Medicine, Omaha, in 1927 and entered the service in June of that year.

Lieutenant Philip B. Phillips

Lieut. Philip B. Phillips, formerly of Portsmouth, Va., was recently awarded the Legion of Merit. He won the award for his action as a flight surgeon, "distinguishing himself by meritorious conduct in the performance of outstanding service. While conducting air operations against Japanese surface task forces his ship was struck and badly damaged by enemy air attacks. Not only was the ship unable to carry on further operations against the enemy because of damage, but casualties were extremely heavy. He treated injured gunners on the deck while enemy planes circled overhead preparing to attack the formation further. He made his way through smoke and flame on the deck, where a bomb exploded, to care for the critically wounded and to provide for their removal to sick bay. For four days and nights he applied his skill to the saving of life and was rewarded by success countless times. His energy, skill and determination were such that his profession may well take pride in him." Dr. Phillips graduated from the University of Arkansas School of Medicine, Little Rock, in 1941 and entered the service in June 1941.

MISCELLANEOUS

DR. JOHN H. STOKES COMMENDED

The Army recently awarded a certificate of commendation to Dr. John H. Stokes, professor of cutaneous medicine and syphilology at both the School of Medicine and the Graduate School of Medicine of the University of Pennsylvania. The citation follows.

". . . For meritorious service to the Third Service Command in the field of venereal disease control, a master clinician and research worker, Dr. Stokes has been engaged in fundamental medical research and teaching throughout his medical career. He has made significant contributions in the treatment and control of syphilis, critically evaluated public health technic and legislation concerned with the control of venereal diseases, not only for his intense devotion to duty and frequent counsel to army venereal disease control officers, has materially assisted in maintaining the health of the armed forces in the Third Service Command."

The presentation was made by Brig Gen. Thomas E. Troland, commanding general, Pennsylvania District, Third Service Command.

Dr. Stokes is one of a number of medical specialists who were appointed by the Army as civilian consultants to the Office of the Surgeon General to work with Brig. Gen. Hugh J. Morgan, chief consultant in medicine He also is special consultant to the United States Public Health Service and a senior surgeon in the United States Public Health Service Reserve.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Birmingham General Hospital, Van Nuys: The Management of Simple Skin Diseases, Lieut. Col. Everett R. Seale, August 8; Anesthesia in War Surgery, Lieut. L. E. Trotter, August 22.

A. A. F. Regional Hospital, Camp Haan: Surgery of the Liver and Its Ducts, Capt. E. E. Larson, August 7.

Camp Cooke Station Hospital, Lompoc: Psychosomatic Medicine, Dr. H. Douglas Eaton, August 15.

U. S. Naval Hospital, Santa Margarita Ranch: Some Dynamics of Military Neuropsychiatry, Major Alex Blumstein, August 9; Intraocular Foreign Bodies, Lieut. Comdr. H. Lusic, August 23.

U. S. Naval Hospital, Corona: Pulmonary Tuberculosis, Comdr. W. L. Rogers and Comdr. A. W. Hobby, August 9; Penicillin in Syphilis and Gonococcic Infections, Lieut. Comdr. W. W. Duemling, August 23.

U. S. Naval Air Training Station, San Diego: Communicable Diseases, Major Norman Nixon and Capt. Charles Marple, August 17.

Santa Ana Army Air Base Regional and Convalescent Hospital: Peritoneoscopy, Capt. J. C. Ruddock, August 7; War Wounds of the Chest, Lieut. Comdr. J. P. O'Connor and Lieut. Henry Jaffee, August 21.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

July 30, 1945.

One-Hundred and Seventieth Birthday of the Army Medical Department

Instead of cutting a birthday cake, the Army unveiled some of the medical advances made during the war, when the 170th birthday of the Army Medical Department was observed at Walter Reed Hospital, with Sir Alexander Fleming, discoverer of penicillin, and some 6,000 Washingtonians present. The new medical processes were described as methods which are enabling more wounded servicemen to be returned mentally and physically sound to their homes than in any previous war. Guests were escorted through typical wards and the artificial limb shops. Sir Alexander met some of the servicemen whose lives his discovery had saved, and he answered their questions regarding the drug. He also disclosed that penicillin will soon be mixed with a new ingredient which will permit the drug to remain longer in the body and require fewer administrations.

Scientific Dependence on Germany Scored by Committee

American dependence on Germany for scientific research was scored by a Senate subcommittee on war mobilization, which suggests legislation to expand research and development by private organizations and the government. In its report the Senate Military Affairs Committee said that since science is decisive in war and peace it must be provided for within the regular framework of government. Its report stated that "only in this way can we become independent of German science, on which we have leaned so heavily in the past. Our people must support basic research instead of relying on basic research evolving from the laboratories of other nations. In addition to philanthropy at home we have depended very heavily on the basic research done in Germany with the support of the German government. Through the cartel system we have also presumably relied on Germany for a great deal of our applied research." In supporting government support of scientific research on the largest scale in American history, the subcommittee said that it was technological development and the "concentration of this advanced technology for aggression" that had carried Germany to "the edge of victory."

Shortage of Office Space for Returning Doctors

Theodore Wiprud, secretary of the Medical Society of the District of Columbia, has again called attention to the shortage of office space in Washington for doctors returning from practice with the armed forces, a serious situation that also exists in many other cities. Mr. Wiprud said, in part, "It seems to us that the public is entitled to know that, if office space in Washington continues to be unobtainable, service physicians returning to civilian life will find it impossible to reestablish themselves in practice. The District Society's Committee on Service Physicians, of which Col. A. Clagett Gray, chief medical officer of the District Selective Service, is chairman, recently called attention to the difficulty a few discharged veterans have already had. During the war a number of buildings which have been, or might have been, used by physicians have been taken over by the government. If the agencies which occupy them are dissolved or their staffs reduced, and the buildings they occupy made available for civilian use, the situation might be alleviated.

Correction of Misstatement in Press

An erroneous impression on the number of doctors in Washington, resulting from a news story in the Washington *Post*, which quoted Dr. Paul F. Dickens, state chairman of the Procurement and Assignment Service, as saying that "Washington has several more physicians than it needs," has been corrected by Dr. Dickens. He has issued this statement: "What I did say was this: 'The Advisory Committee to the State Chairman for Procurement and Assignment Service for Physicians, after a careful survey of the situation, advised that 910 physicians was the minimum number necessary to care for the basic health and comfort of the community and we should not withdraw physicians from the community below that number. It is estimated that as of this date we have perhaps 922 physicians practicing medicine in the metropolitan area. Many of these physicians are in the upper age bracket and certainly need a rest. Some of the physicians now practicing in this community previously had retired and to help the war effort came back into the practice of medicine.'"

Inspection of Hospitals by House Veterans Committee

Unannounced inspections of veterans' hospitals throughout the country are being made by members of the House Veterans' Committee during the House recess in order that they may be ready with concrete information for resumption of the committee's investigation in the fall. They are also discussing veterans' hospital problems with the managers and medical officers. Extensive changes are expected to be made in the Veterans' Administration medical setup under Gen. Omar T. Bradley, who will succeed Brig. Gen. Frank T. Hines on August 15. Representatives expect that future committee hearings will explore legislation designed to improve the medical service and discover present shortcomings. Early in October Chairman Rankin will take up a pending bill which would set up in the Veterans Administration a bureau of medicine and surgery similar in scope and authority to the Army Surgeon General's Office and the Navy Bureau of Medicine and Surgery. In favor of this legislation in principle are Representative Rogers of Massachusetts, ranking minority member, and a number of others. As yet General Bradley has not expressed himself on proposals to reorganize the Veterans Administration. Several physicians of national prominence, who testified at hospital hearings, favor the medical bureau, but with a strictly civilian staff.

Presentation of Humanitarian Award to Sir Alexander Fleming

Sir Alexander Fleming, Scottish scientist who discovered penicillin, was awarded the Variety Clubs' Humanitarian Award for 1944 before cabinet members, diplomats and representatives of the United Nations. At the Mayflower Hotel a letter from President Truman was read by Secretary of the Treasury Fred M. Vinson describing Sir Alexander as a man "to whom the world owes a debt of gratitude difficult to estimate." Sir Alexander was the sixth person and the first Briton to receive the silver plaque and the honorarium of $1,000. He was nominated as the man "whose humanitarian efforts have contributed most to the welfare of mankind" in 1944. R. J. O'Donnell, national chief barker of the Variety Clubs of America, an organization of the show business, presented the award, which recognized the scientist for his "faithful and diligent efforts" in medical research, "which have meant so much toward the alleviation of pain and suffering."

Limited Quantities of DDT Released to Civilians

Civilians will get limited quantities of DDT in August. The War Production Board reports that release of the powerful insecticide developed in this war for military use has been made possible by increased production. To date, civilian and agricultural use of the insecticide has been restricted to experimental purposes. The agency cautions that "there is a great deal that is yet to be learned about how to use DDT insecticides safely." DDT has proved effective in killing mosquitoes, cockroaches, flies, bedbugs and other insects.

Postwar Medical Service

MINUTES OF MEETING OF JUNE 23

The Committee on Postwar Medical Service met on Saturday, June 23, 1945, in the Board of Trustees Room of the American Medical Association Building in Chicago. The meeting was called to order by the Chairman, Dr. Ernest E. Irons, at 10 a. m. Those present were:

Dr. *Louis H. Bauer, Trustee, American Medical Association.*
Lieut. Col. R. D. Bickel, Liaison Officer, Office of the Surgeon General, U. S. Army, and the American Medical Association.
Dr. Walter L. Bierring, Federation of State Medical Boards.
Dr. Francis G. Blake, American Medical Association Committee.
Capt. W. E. Eaton (MC), U. S. Navy, American Medical Association Committee.
Dr. Morris Fishbein, American Medical Association Committee.
Dr. E. L. Henderson, American Medical Association Committee.
Mr. J. W. Holloway Jr., Director, Bureau of Legal Medicine and Legislation, American Medical Association.
Dr. Ernest E. Irons, American College of Physicians Committee.
Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals, American Medical Association.
Dr. Edwin P. Jordan, Associate Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.
Dr. B. R. Kirklin, Advisory Board for Medical Specialties.
Dr. H. L. Kretschmer, President, American Medical Association.
Dr. Roger I. Lee, President-Elect, American Medical Association.
Lieut. Col. H. C. Lueth, Office of the Surgeon General, War Department.
Col. Hugo Mella, Veterans Administration.
Col. F. V. Meriwether, U. S. Public Health Service.
Dr. J. J. Moore, Treasurer, American Medical Association.
Col. George M. Powell, Office of the Surgeon General, War Department.
Brig. Gen. Fred W. Rankin, Office of the Surgeon General, War Department.
Father A. M. Schwitalla, S.J., Catholic Hospital Association.
Dr. R. L. Sensenich, Trustee, American Medical Association.
Dr. H. H. Shoulders, American Medical Association Committee.
Dr. LeRoy H. Sloan, American College of Physicians Committee.
Dr. Olin West, American Medical Association Committee.

Approval of Minutes.—The minutes of the Committee meeting held on May 12, 1945, as circulated, together with minor corrections suggested by Drs. Sloan and Bierring, were presented by the Chairman, and the corrected minutes were approved.

Committee Membership.—The Chairman informed the Committee that Dr. Walter W. Palmer of New York had accepted reappointment by the American College of Physicians as a member of the Committee on Postwar Medical Service to succeed Dr. W. W. Herrick, deceased.

Communication from Miss Switzer.—A telegram from Miss Mary Switzer, liaison member of the Committee representing the Procurement and Assignment Service, was presented. The communication dealt briefly with the supply of medical and dental students and with the surplus property situation.

Dr. Fishbein supplemented the information offered in Miss Switzer's telegram. He said that the deferment of medical and dental students is being considered in Washington through an interdepartmental committee. He also stated that the advisory committee on surplus property to be appointed by Mr. McNutt probably will contain representatives of the American Hospital Association, the American Medical Association, the American Dental Association, the Conference of State and Territorial Health Officers, the Conference of State Sanitary Engineers and others. This advisory committee, with Surgeon General Parran as chairman, will set up a policy for the disposal of surplus medical and hospital supplies. He touched briefly on the preliminary conference on this matter which he and Dr. Irons had attended in Washington some weeks ago. (A report of this conference appeared in the minutes of the Committee's May 12 meeting.)

Bureau of Information.—The following report on the status of the work of the Bureau of Information, prepared by Lieutenant Colonel Bickel, was presented by Dr. Jordan:

The Bureau of Information is developing along the lines originally established. The work of securing information from counties about the need for doctors has been the most difficult part of establishing the Bureau, but the problems having to do with education and licensure have been more easily handled, as the result of the cooperation of the Council on Medical Education and Hospitals and the Bureau of Legal Medicine and Legislation. During recent weeks there has been a gratifying increase in the number of completed county summary sheets received from the state medical societies. However, there are still many counties to be heard from, and continued efforts are being made to complete this part of the program.

Twenty-one states, as of June 22, 1945, have returned completed summary sheets for each county in the state. Twenty state medical societies have sent in completed summary sheets for some of the counties in their states. A total of 1,981 county summary sheets have been received from all of these states. Eight states, including a total of 247 counties, have made no returns, although some of these states are completing their data and it is expected that this material will be received soon.

The following facts illustrative of the beginning of the service of the Bureau of Information may be of interest: Approximately 106 physician veterans have asked for information about places in which to establish a practice; fifty different localities have communicated with the Bureau through local civic groups and others in an effort to secure physicians to practice in these areas, and there have been approximately fifty personal interviews with physician veterans who were interested in obtaining residencies, other hospital appointments or information about likely places in which to begin practice.

Recently work has been started on an information pamphlet which will describe the facilities of the American Medical Association for aiding returning physicians. This should be helpful to physicians in their problems of education, licensure and medical practice. This pamphlet includes material prepared by the Council on Medical Education and Hospitals, the Bureau of Legal Medicine and Legislation and the Bureau of Information.

Dr. Jordan presented galley proofs of the proposed Information Bulletin for Medical Officers, and it was the Committee's opinion that the information contained therein will be of interest and benefit to all medical officers. The proposed bulletin was approved subject to corrections or additions which may be offered by members of the Committee, and authorization was given for its widest possible distribution to the medical members of the armed forces, including those now on active duty and those who may be in process of separation from active service.

Various suggestions were offered as to the distribution of the bulletin: It was felt that it should be sent to any individual medical officer who may write to the Committee on Postwar Medical Service, placed in the hands of medical officers at separation centers and made available to the Surgeons General of the Army, Navy and Public Health Service for possible distribution by means of insertion in the medical bulletins of those services. It was also suggested that copies might be distributed on an individual basis through the offices of the surgeons of the various service commands and might also be circulated from the offices of the state Procurement and Assignment agencies.

Colonel Powell agreed to present to the Surgeon General of the Army the request that the pamphlet be inserted in an early issue of the *Army Medical Bulletin*, and Captain Eaton agreed to present the request to the Surgeon General of the Navy that it be inserted in the *Naval Medical Bulletin*. Colonel Meriwether stated that he would ask General Parran if it could be inserted in the Public Health Service bulletin. It was the opinion of the Committee that it would be desirable to carry out all of these suggestions.

The Chairman stated that a further report from the Bureau of Information would be requested at the next meeting.

Progress Report on the Availability of Residencies and Short Courses for Physician Veterans.—Dr. Johnson presented the following report, which, after discussion, was accepted:

Responses from hospitals which are expanding their facilities indicate that approximately 28 per cent of the 1,054 civilian hospitals approved for internships and/or residencies probably will be in a position to supply approximately 42 per cent of the overall demand for increased house officerships. This would indicate that when all hospitals have completed their plans the demand, in all probability, will be met.

There is a special need for providing additional places in surgery where nearly 1,600 physicians probably will seek training, and at present only about one fourth of this number appears to be available.

The expanded number of places in approved hospitals will be indicated in the next printing of Approved Residencies and Fellowships in September 1945. This will constitute the first list which includes facilities especially for veterans and will be so labeled.

In the next semiannual publication of continuation courses, which will appear in THE JOURNAL in July, there will be included a considerable number of special courses which have been developed to meet the needs of physician veterans. This will also constitute a first publication of such courses and will be entitled "Continuation Courses for Veteran and Civilian Physicians."

These lists will be incomplete, since not all institutions have fully formulated their plans, but the lists can and will be modified on republication in accordance with further expansion of educational facilities.

In the discussion of Dr. Johnson's report, it was mentioned that there is a definite relationship between the philosophy of demobilization and the availability or nonavailability of residencies. Father Schwitalla asked if there had been a very great demand for additional places in anesthesiology in the civilian hospitals independent of the increase coming through the physician veterans. He commented that the nurse anesthetist organizations are using the reported demand as an argument for recruitment and that what he said with respect to anesthesiology might also apply to the field of radiology and to other special

Expansion of Residencies in 292 of the 1,054 Civilian Hospitals Approved for Internships and/or Residencies

Field of Training	Estimated Requirement (2 Year Demobilization)	Additional Residencies Available in 292 Hospitals
Anesthesiology	71	102
Dermatology and syphilology	108	54

Surgery and subspecialties	1,595	416
Urology	108	78
Other fields	34	..
Totals	5,727	2,382

fields, the argument in all cases being on the basis that there are not enough physicians to fill the need. Dr. Johnson agreed that this is a vital problem.

Father Schwitalla stated that there has been a growing tendency toward specialization among recent graduates and that a 15 per cent increase in the desire for residencies in the various specialties must be anticipated. He wondered if this was not a dangerous situation with respect to the future of medical practice. In reply, Dr. Kirklin stated that the specialty boards are trying to take care of the problem and that while there seems to be a general feeling among the members of the profession that the boards may lower their standards for the benefit of the men returning from service, the fact is that the standards are being kept up to where they always have been and even may be raised a little higher. He further stated that the Advisory Board for Medical Specialties had discussed, at length, credit that might be allowed for military service and that such credit had been considered by every one of the specialty boards. General Rankin stated that the American Board of Surgery allows its candidates a year's credit for military service provided that service has included hospital training, and Dr. Kretschmer said this was also true of the American Board of Urology, as did Dr. Irons of the American Board of Internal Medicine. Dr. Moore informed the Committee that the American Board of Pathology gave credit for military service only if such service or a sufficient part of it had been in a laboratory.

Refresher Courses for Army Medical Officers.—Colonel Powell reported that since the May 12 meeting the following information concerning refresher courses for medical officers had been made available:

Refresher training for medical officers will be conducted in the European Theater of Operations during the period of redeployment.

In military installations, basic refresher courses starting July 1, 1945 are to be taught at hospital centers and at general and station hospitals and will include general surgery and general medicine eight weeks, and anesthesia, radiology, psychiatry, clinical psychology and dermatology four weeks. Also in military installations there will be advanced courses of three months' duration in medical specialties starting July 1, 1945 at hospital centers and at general and station hospitals, which will include infectious diseases, cardiovascular diseases and gastroenterology.

It is proposed to begin refresher courses in civilian agencies by June 18, 1945 at the earliest, to be in progress by July 15. Refresher courses in basic general medicine and surgery—four weeks—are to be given at eleven London medical schools, Glasgow University and the University of Paris, and in general surgery—six weeks—at Edinburgh University, the University of Paris, eleven London medical schools and the British Post-Graduate Medical School. Advanced courses of six weeks' duration in obstetrics and gynecology will be given at the British Post-Graduate Medical School, the University of Paris and Edinburgh University, and a basic course of four weeks in the same subjects at Queen Charlotte Hospital. A six weeks course in neurology and psychiatry will be taught at the University of Paris, and an advanced course in radiology will be provided under the proctor system with one student per British radiologist.

In a recent communication from the European Theater of Operations, requests for availability of training material in preventive medicine, particularly tropical diseases, indicate that such courses are contemplated.

These courses will provide refresher instruction in military installations to 965 medical officers and in civilian agencies to 425 medical officers.

It was stated by Colonel Powell that in addition to the foregoing there are now 177 officers in the courses established for the Army Service and Ground Forces, and that the Air Forces also have courses.

Lieutenant Colonel Lueth stated that the Office of the Surgeon General had established a card reporting system for the returning medical officer, who fills out the card questionnaire indicating his desire for refresher courses as he arrives at a reception station. As the medical officer returns he is grounded for thirty days' temporary duty at home, which gives the office enough time to assign him; this scheme is designed to be of service to those officers who do not stay in Europe long enough to take advantage of the courses offered in the European Theater of Operations. He added that the Air Forces have nearly 100 men registered in their refresher courses.

After discussion as to the method of teaching and the manner in which the faculties are arranged, Colonel Powell's report was received.

Enrolment of Medical Students.—Dr. Johnson, Chairman of the Subcommittee on Enrolment of Medical Students, reported that Dr. Evarts Graham, who was made a member of the subcommittee at the May 12 meeting, was instrumental in arranging an interview with the President on May 31; present at this interview were Dr. Graham, Dr. Johnson, Dr. Harvey Stone and Dr. Zapffe. Since the President undoubtedly will confer with the military authorities on this problem, attempts are being made to arrange an interview with the Chief of Staff, and Dr. Stone has reported that he thinks it will be possible to arrange such an interview in the near future. Further plans are under way for bringing the matter to the attention of the people.

The Chairman presented a memorandum which the subcommittee had submitted to the President, and Father Schwitalla requested that it be published. (This memorandum was printed in THE JOURNAL, July 21, p. 884.)

The report of the subcommittee was accepted.

National Research Foundation.—Dr. Fishbein gave an outline of a report recently made by Mr. Vannevar Bush dealing with future government activity in connection with scientific research. He stated that he had been requested by the Board of Trustees of the American Medical Association to present the matter to the Committee on Postwar Medical Service with a view to the establishment of a group or subcommittee to study the report as soon as it becomes available and report back to the Committee so that a policy on this subject may be formulated.

The Chairman was authorized to appoint a subcommittee to study the Bush report when it becomes available and to make recommendations to the Committee on Postwar Medical Ser-

vice. The following subcommittee was appointed: Dr. Francis G. Blake, chairman; Dr. Victor Johnson, Dr. Frederick A. Coller, Father A. M. Schwitalla and Dr. Walter W. Palmer.

Surplus Medical and Hospital Supplies.—Father Schwitalla, chairman of the Subcommittee on Surplus Medical and Hospital Supplies, stated that he had no information beyond what had been submitted earlier in the meeting.

Dr. Fishbein said that it is proposed that the advisory committee which Dr. Parran is to appoint draw up a schedule of the minimum equipment necessary for a physician going into a rural district, and the Surplus Property Board will be able to rent the equipment to such a physician for five years at an annual rental of $1, thus encouraging the establishment of a physician in a needy area. He also stated that there is included in the surplus property that will be available a great deal of equipment left over from World War I, and that it is desired to set up a system whereby much of this old, obsolete and in many cases worthless and possibly harmful material can be destroyed. He further stated that there will be a distributing station in each state and that priorities are to be given to all returning medical officers, who will be entitled to a special discount. It is expected that disposal of the surplus property will be accomplished within three years after the close of the war.

Dr. Bierring described the system of distribution contemplated in Iowa.

The Chairman brought to the attention of the Committee the report submitted by Father Schwitalla at the meeting of the Committee on March 17, 1945, and Father Schwitalla stated that the informational part of the original report was still up to date but he would prefer that final action on it be deferred until the next meeting of the Committee, at which time it is hoped that more and newer information will be available.

The subcommittee was continued to report at the next meeting.

Veterans Administration.—Replies to Statement on Transfer of Medical Officers: The Chairman read for the information of the Committee replies to the statement protesting the transfer of medical officers to the Veterans Administration, which was adopted by the Committee at the May 12 meeting and sent to the Secretary of War and the Secretary of the Navy.

The Chairman stated that a telegram had just been received by the Editor of THE JOURNAL from Surgeon General Kirk in which it was stated that "In the future Medical Corps officers will not be assigned to the Veterans Administration unless they were previously employed by that agency or they specifically request such assignment."

Report of Subcommittee to Confer and Cooperate with Veterans Administration: Father Schwitalla, chairman of the subcommittee, referred to recent instructions issued by the Veterans Administration in connection with educational opportunities offered under the G. I. bill. He stated that provision is made for recognition of lists of institutions maintained by established accrediting agencies, and that such approved institutions need not be investigated. The accrediting agencies so recognized are:

American Association of Teachers' Colleges
American Association of Theological Schools
American Bar Association
American Council on Pharmaceutical Education
American Osteopathic Association
Association of American Universities
Council on Dental Education, American Dental Association
Council on Medical Education and Hospitals, American Medical Association
International Association of Boards of Examiners in Optometry
Middle States Association of Colleges and Secondary Schools
National Association of Schools of Music
National League of Nursing Education
New England Association of Colleges and Secondary Schools
North Central Association of Colleges and Secondary Schools
Northwest Association of Secondary and Higher Schools
Southern Association of Colleges and Secondary Schools

Father Schwitalla raised the question as to whether or not an intern who is receiving a small intern stipend from a hospital is entitled to receive the maintenance benefit provided for student veterans, and Dr. Johnson made the following statement:

Conferences and subsequent correspondence have been had with Mr. H. V. Stirling, director of the Vocational Rehabilitation and Education Service of the Veterans Administration, regarding the case of Dr. Henry I. Colman, who applied for benefits under the G. I. Bill of Rights while he was taking a nine months course as an intern in obstetrics and gynecology at the Bellevue Hospital in New York. He had been refused subsistence benefits by the Veterans Administrator in New York City on the grounds that he was already receiving compensation from the hospital in the form of maintenance and a stipend. Mr. Stirling made a clearcut ruling in this case, which should serve as a precedent for similar instances of this kind that are very likely to arise elsewhere in this country. Among other things, Mr. Stirling stated the following in his letter to the Veterans Administrator in New York City:

"It has been determined that where a person is pursuing on the job training and receiving compensation for productive labor as a part of the course of training on the job, he may be paid subsistence allowance provided the sum of the amount he received from the employer-trainer and his subsistence allowance do not exceed what is considered to be the beginning salary or compensation for persons qualified to perform the duties and functions of the position for which training is being pursued. Subsistence allowance may be reduced to a lesser amount not to exceed the amount of the difference between the compensation for productive labor as a part of his training on the job and the beginning salary or compensation for a person who has completed the type of training being pursued.

"If the facts in this case are shown to be in substantial agreement with those stated, it is considered that subsistence allowance may be awarded this veteran from the date of his application, formal or informal, or the date he entered training, whichever is the later. It is believed the compensation received by Dr. Colman plus the full amount of subsistence allowance does not exceed a reasonable beginning salary for a physician skilled in the specialty for which he is receiving training."

It was the consensus of the Committee that Mr. Stirling's communication completely sustained the statement on the payment of salaries under the G. I. bill that was contained in the report of Father Schwitalla's subcommittee presented at the May 12 meeting, and that Mr. Stirling's interpretation established a precedent.

A letter received from a veteran who wished to know whether or not he could study part time under the G. I. bill was presented by the Chairman, and Colonel Mella informed the Committee that the medical service had obtained a ruling that a veteran may utilize half days or evenings for his educational program; there is a time limit of a year or more, depending on the veteran's length of service, but if he is entitled to one year's training and attends his course only half time then he actually can spend two years in his educational pursuits; that is possible under the law and there has been a very definite ruling; however, each case is handled on an individual basis. Colonel Mella noted that this matter is covered in the proposed Information Bulletin for Medical Officers previously discussed.

The report of the subcommittee was received and the committee continued.

Report of Subcommittee on Establishment of a Medical Corps in the Veterans Administration: Father Schwitalla, chairman of the subcommittee, stated that he had been informed that the bills for the establishment of a Medical Corps seem to be dead, and that perhaps nothing will be done until the new administrator has had time to familiarize himself with the entire problem. He thought that the subcommittee might be discontinued, but Colonel Mella thought it would be unfortunate if the subcommittee was discontinued at this time with all the changes that undoubtedly will soon be made, and also that the statement as to the bills being dead was not official.

The subcommittee was continued with the expectation that matters with which it is concerned will again be taken up at the next meeting.

The Governors and the G. I. Bill.—Dr. Shoulders, chairman of the Subcommittee to Draw Up Recommendations to the Governors of the States Concerning the G. I. Bill of Rights, gave a short analysis of the replies of various state governors to the recommendations forwarded to them in accordance with the action of the Committee on Postwar Medical Service at its meeting in March.

The chairman stated that the reception of the "Governors' Letter" had, on the whole, been very favorable and cordial.

The report of the subcommittee was received.

Demobilization of Medical Officers.—Dr. Johnson, chairman of the Subcommittee on Formulation of Lists of Medical Officers to be considered for Demobilization, presented the following report:

Communications have been sent to the deans of the schools of public health and to the public health officers of each state requesting the names of public health teachers and officers whose release would relieve critical shortages. Many states and schools have already reported. The names of these individuals have been submitted to the Office of the Surgeon General of the Army in the same manner that the names of critically needed teachers in medical schools were submitted. The original instructions of the Committee on Postwar Medical Service to the subcommittee concerning the release of essential teachers included investigation of these fields of public health. Likewise, in his original request to the subcommittee for lists of essential teachers, the Surgeon General indicated a desire to have names of public health officers as well. As further names are submitted they will be transferred to the Office of the Surgeon General.

Dr. Rankin reported that Dr. Morgan, Dr. Menninger and himself with the assistance of heads of technical services had gone over the lists to determine the military essentiality of the officers involved; that there are a number on the list who cannot be released; that at present the list is incomplete but it appears that it may be possible to release 233 medical officers, 121 of whom are unfortunately not in this country; that 5 essential teachers already have been released from service; that there should be a considerable number discharged by the time of the next meeting of the Committee, and that the list can be supplemented by substitutions and additions from time to time.

Captain Eaton stated that this matter is being carefully considered by the Surgeon General of the Navy, and Lieutenant Colonel Lueth said that there would be about 20 names on the Public Health Service roster to be added to the 233 mentioned by General Rankin.

Licensure.—A résumé of several letters that had been received inquiring as to the conditions of licensure that will apply in the case of returning medical officers was given by the Chairman.

Dr. Bierring reminded the Committee of the report made by him at a previous meeting in which he had stated that it was the considered opinion of the Federation of State Medical Boards that the question of special consideration for veterans who are applicants for license is an individual matter to be left to the individual state boards. He stated that the matter is being pushed particularly by graduates of unapproved schools; that the Federation has received letters from United States senators, and that an attempt is being made to arouse popular sentiment.

There was lengthy discussion of H. R. 2969, recently introduced by Congressman Eberhardt. It was thought that this bill may be the forerunner of other forms of legislation designed to make it easier for discharged medical officers, particularly the graduates of unapproved medical schools, who wish to locate in a state other than that in which they formerly were licensed, to secure a license—and perhaps to avoid examination—under more liberal conditions than now prevail.

Dr. Bierring remarked that the reciprocity agreements between states and the fact that many of the medical officers are diplomates of the National Board of Medical Examiners should take care of some of the difficulties, and that by the time the Committee meets again more information will be available. The Chairman stated that it is quite beyond the function of the Committee on Postwar Medical Service or of the Board of Trustees of the American Medical Association to tell any state licensing board what it should do, but he thought the matter should be brought to the attention of the state boards.

Informational Reports.—Wartime Graduate Medical Meetings: Dr. Shoulders reported for Dr. F. F. Borzell that it is becoming increasingly difficult to supply speakers for the programs sponsored by the Wartime Graduate Medical Meetings and that it has been suggested that the Army and Navy might be willing and able to supply medical officers for this purpose. Captain Eaton said he would present the matter to the Surgeon General of the Navy, but he thought that some arrangements could be made locally, which had already been done in some cases. It was suggested by the Chairman that Dr. Borzell might himself communicate with the Surgeons General and request their assistance.

Navy Department: Captain Eaton presented a pamphlet prepared by the Professional Division of the Bureau of Medicine and Surgery entitled "Essentials of Internship and of Residency-Type Training in United States Naval Hospitals."

Time and Place of Next Meeting.—It was decided that the next meeting of the Committee will be held at American Medical Association Headquarters in Chicago on Saturday, Sept. 22, 1945, and that if matters of emergency should arise in the meantime they can be referred to subcommittees or, if necessary, the Chairman will call a meeting of the Committee.

The meeting adjourned at 12:35 p. m.

H. H. Shoulders, M.D., Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Maternal and Child Welfare Act of 1945

Senator Pepper, Florida, for himself and nine other members of the Senate Committee on Education and Labor, has introduced S. 1318 to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children. This bill would authorize an appropriation of $100,000,000 for the fiscal year ending June 30, 1946: $50,000,000 for maternal and child health services, $25,000,000 for services for crippled children, $20,000,000 for child welfare services and $5,000,000 for administrative expenses incurred by the Children's Bureau in carrying out the provisions of the bill. Thereafter such sums will be made available as the Congress may decide.

Army Optometry Corps

A bill to establish an Optometry Corps in the Medical Department of the Army, H. R. 3755, has been reported by the House Committee on Military Affairs with the recommendation that it pass. Officers of the proposed Optometry Corps will be assigned to optometrical duty or to administrative duty in connection therewith. When assigned to optometrical duty, they are to perform optometrical work determined on by a medical officer, who is required to be an ophthalmologist. The right of officers of the Optometry Corps to command, it is proposed, will be limited to command within the Optometry Corps and the Medical Administrative Corps. Provision is made for Optometry Corps reserve units.

Dental Research

Representative Priest, Tennessee, has introduced H. R. 3816 to provide for, foster and aid in coordinating research relating to dental diseases and conditions and to establish the National Institute of Dental Research. Congressional hearings have recently been held on previous bills relating to this subject.

Hospital Construction

A bill substantially similar to the Hill-Burton hospital construction bill, S. 191, was introduced in the House of Representatives, July 18, by Representative Snyder, Pennsylvania. H. R. 3845.

Bureau of Information

The Bureau of Information has prepared and has begun the distribution of a questionnaire to civilian physicians. Physicians in Iowa and Florida have already been mailed their questionnaires, and those in other states will receive theirs soon.

In accordance with the obligation of the Bureau to collect as complete data as possible on the distribution of physicians and other aspects of medical practice, it is hoped that physicians will return their questionnaires promptly so that the files of the Bureau will be more complete and up to date.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST, SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Officers of State Medical Board.—At a meeting June 8 of the state medical board Dr. Robert J. Haley Jr., Paragould, was chosen president, Dr. Robert H. Hood, Russellville, vice president and Dr. Leonce J. Kosminsky, Texarkana, secretary-treasurer. Other members of the board include Drs. John B. Jameson, Camden, Jasper T. Matthews, Heber Springs, John M. Proctor, Hot Springs National Park, and William H. Poynor, Harrison. Dr. DeVeaux L. Owens, Harrison, was retired after serving eight years on the board, which is the allowed time. Dr. Eugene A. Callahan, Carlisle, also served eight years but died May 28, preceding the June 8 meeting.

CALIFORNIA

Personal.—On June 23 the University of Southern California, Los Angeles, conferred the honorary degree of doctor of science on Dr. Walter L. Treadway, Los Angeles, formerly assistant surgeon general of the U. S. Public Health Service.——Dr. William McDowell Hammon, associate professor of epidemiology in the George Williams Hooper Foundation for Medical Research, University of California, San Francisco, accepted a similar appointment in the school of public health on the Berkeley campus, effective July 1. Dr. Hammon, who will continue his association with the Hooper Foundation, will be responsible for developing training programs in epidemiology in the school of public health.

Equalization Board Revises Ruling on Sales Tax.—The California Board of Equalization on June 11 reported to the American College of Radiology a revision of its ruling specifying that the physicians engaged in the specialty of radiology should be subject to a state sales tax on films used. The sales tax now, stated the board, would be applied only in those cases in which the radiologist or commercial laboratory delivers to patients films employed in their examination. On April 7 the college of radiology filed a brief contesting the original ruling of the board of equalization, which stipulated that the radiologists would be required to pay a sales tax on that portion of fees charged by them which represent a "fair retail value of x-ray pictures or negatives" employed in the examination of patients. A similar action took place in New York (THE JOURNAL, April 28, p. 1141).

COLORADO

Occupational Disease Compensation Law.—Occupational diseases become compensable for the first time in the history of the state, under a law passed by the general assembly of Colorado recently. The act goes into effect Jan. 1, 1946. Coverage is limited to diseases listed in a schedule which includes silicosis and asbestosis. According to the *Industrial Hygiene News Letter* the Colorado division of industrial hygiene cooperated in drafting the bill. Colorado is the twenty-ninth state to adopt a law compensating for industrial disease.

CONNECTICUT

Personal.—Dr. James H. Naylor, Hartford, recently received an honorary degree of doctor of laws from the University of Vermont, Burlington, where he graduated in medicine in 1895.

Student Membership.—Two hundred and eight medical students whose family residence is in Connecticut have been elected to student membership in the Connecticut State Medical Society by the council of the society. The student members are enrolled at twenty-five medical schools, with nearly 50 per cent registered at the Yale, Long Island, Tufts, University of Vermont and Boston University medical schools. Fifty-nine Connecticut towns and cities are represented on the list of home addresses of the new members, who are at various stages in the study of medicine ranging from the first year to internship. The student members will be affiliated with the county medical associations in the counties where they reside and will share in the privileges and participate in the activities of these organizations except that they may not vote or hold office.

ILLINOIS

Physician Named "Man of the Week."—Dr. William R. Roberts, Cissna Park, was recently chosen "Man of the Week" by the Danville *Commercial News*. In his nomination for the honor, credit was given to Dr. Roberts for his service to the community and his recent admission to membership in the fifty year club of the Illinois State Medical Society. Two of his sons, both physicians and now in service, were formerly associated with him.

KENTUCKY

Personal.—Dr. John O. Salyers has been appointed full time resident physician at the State Reformatory Hospital, La Grange, effective July 16.——Dr. Bertha A. C. Wiseman, La Grange, health director of Oldham County, has been assigned to the Shelby County Department of Health temporarily until a full time director can be named to succeed Dr. Martin H. Skaggs, resigned (THE JOURNAL, June 30, p. 676).

Eight Attend Fifty-Second Class Reunion.—Eight physicians of 224 members of the class of 1893, Kentucky School of Medicine, assembled for a reunion June 21 at the Henry Clay Hotel, Louisville. Thirty-five members of the class are still living. The eight physicians who attended the reunion are Drs. Maurice Bell, Eminence; Charles C. Crampton, Delphi, Ind.; Pinkney H. Crutchfield, Stamping Ground; Ross H. Gregory, Fontanelle, Iowa; Richard W. McCracken, Union Grove, Wis.; James H. Morrison, Hartsville, Ind., and Harry S. Noble, St. Marys, Ohio. Dr. James W. Fitch, Portsmouth, Ohio, one of the charter members of the group, was ill and unable to attend.

LOUISIANA

University News.—Dr. John C. Henthorne, Jackson, Miss., was recently appointed assistant professor of pathology at Tulane University of Louisiana School of Medicine, New Orleans. Dr. Alton Ochsner, professor of surgery at the school, was recently given the title of member honoris causa of the College of Physicians and Surgeons of Costa Rica. Dr. Wilbur C. Smith, professor of gross anatomy at Tulane, has been elected president of the National Collegiate Athletic Association. Dr. Roscoe LeRoy Pullen, instructor in medicine on the Tulane faculty, was chosen by Knox College, Galesburg, Ill., as recipient of the award for the alumnus who has done the most for humanity during the year, it was announced, June 11. Dr. Pullen, who graduated at Knox in 1935 and received his medical degree at Northwestern University Medical School in 1940, has been connected with Tulane since 1941 and is the first physician to have received the award in eight years.

Commencement Activities.—An oil portrait of Dr. Urban Maes, professor and director of the department of surgery, Louisiana State University School of Medicine, New Orleans, the work of William Branks Stewart, medical artist, was presented to the school by the graduating class during the recent commencement exercises. Dr. Morris Fishbein, Editor of THE JOURNAL, spoke on "Medicine in the Postwar World." Dr. Joyce Wofford Odell received the George S. Bel Memorial Award of $50, having been voted by the faculty as the leading member of the class. This award is given by Mrs. Elsie Bel in memory of her late husband, Dr. George S. Bel, who was formerly professor and director of the department of medicine at the school. Dr. Odell also received the A. J. Majors Medical Book Company Award of a book, which is presented for exceptional scholarship in courses offered by the department of pathology and bacteriology. Dr. William H. Stewart received the Hull award, which is presented to the foremost senior member of the Society of Medical Sciences of the school of medicine.

MISSOURI

Appointments to Cancer Commission.—Members of the state cancer commission, in accordance with recent appointments by Governor Phil M. Donnelly, include Dr. Major G. Seelig, St. Louis; Dr. Clifton Smith, St. Joseph; W. Ed Jameson, Fulton, and Frank T. Hodgdon, Hannibal.

Professors Retire.—Dr. Frank C. Neff, Kansas City, on June 30 retired as professor and head of the department of pediatrics, University of Kansas School of Medicine, Kansas City, Kan., and has been succeeded by Dr. Herbert C. Miller Jr., New Haven, Conn. Dr. Neff has been associated with the medical school since 1924. He was formerly a member of the Section on Pediatrics, American Medical Association.

Dr Edward J Curran, Kansas City, retired as professor of ophthalmology and head of the department He has been succeeded by Dr John A Billingsley, Kansas City, Kan

NEBRASKA

Fifty Years of Practice.—Dr Francis P Dorsey Sr, Wayne, was given a dinner by the Five County Medical Society recently in honor of his completion of fifty years of practice——Dr George A Harris, Valley, was recently given a dinner by the Valley Chamber of Commerce in recognition of his completion of fifty years in the practice of medicine

NEW YORK

New Professor of Physiologic Chemistry.—Wilfred W Westerfeld, Ph D, associate in biochemistry, Harvard Medical School, Boston, has been appointed professor of physiologic chemistry at Syracuse University College of Medicine, Syracuse, effective October 1 Dr Westerfeld succeeds Dr Robert K Brewer, who died in March

Cancer Teaching Day.—On October 3 a clinical cancer teaching day will be held at the Homer Folks Tuberculosis Hospital, Oneonta, under the auspices of the Medical Society of the County of Otsego, Sixth District Branch of the state medical society, Tumor Clinic Association of the State of New York, the state medical society and the state department of health's division of cancer control Speakers will include

Dr Gray H Twombly New York, Ovarian Carcinoma
Dr Norman Treves New York Cancer of the Breast
Dr William A Milner, Albany Carcinoma of the Bladder
Dr Fred W Stewart, New York Biopsy in Tumors

Gastroenteritis from Cream Filled Pastries.—*Health News* reports a series of outbreaks of gastroenteritis from cream filled pastries Nine known cases in two counties were reported in one outbreak, all of which were traced to a cream filled cake, prepared by a single bakery, which had been without refrigeration from the time of its preparation until it was consumed twenty-four hours later Fifty-eight known cases were reported in a second outbreak The common source was again traced to a filling in cream cake and chocolate éclairs which had been allowed to stand at room temperature for a period of twenty-four hours following their preparation by a baker who had just recovered from an upper respiratory infection and sore throat Large numbers of hemolytic Staphylococcus aureus organisms were observed in cake and eclairs Early in the year about 100 cases of gastroenteritis occurred in a city in the western part of the state One of the patients died Again the illnesses were traced to chocolate eclairs and cream puffs which had not been properly refrigerated by the bakery concern

New York City

Dr. Ray Dies—George B Ray, Ph D executive director of the department of physiology and pharmacology, Long Island College of Medicine, Brooklyn, died July 6, aged 52

Standards for Hospital Supplies—Columbia University is offering a group of courses on standards of quality for institutional supplies and medical and surgical supplies, medical terminology and medical records According to James U Norris, president of the Hospital Bureau of Standards and Supplies, this represents an educational effort on standards for hospital supplies designed primarily for those persons on hospital staffs who are purchasing commodities of one kind or another Instruction will be given by Dewey H Palmer, M S, research director, Hospital Bureau of Standards and Supplies, Eleanor Lee, A B, assistant professor of nursing, Columbia University, and Dorothy L Kurtz A B, supervisor of the record department, Presbyterian Hospital Additional information may be obtained from the Secretary of Columbia University, 116th Street and Broadway, New York 27

Student Prizes—On June 28 during the eighty-seventh commencement exercises of the Long Island College of Medicine, Brooklyn Lieut Ehah Maurice Nadel M C received three of the eleven prizes given annually to members of the graduating class He won the Nathan H and Johanna Szerlip Medal, given for the best thesis on pneumonia the Jeannette Millman Memorial Award, for the best essay or report on some subject in the field of tumors and the Robert R Benedict Jr Prize, for the best report on a psychiatric problem Top honors in the graduating class went to Dr Frances Anderson Greenwood, Tuscaloosa, Ala who received the Mitchell Prize, awarded to the member of the class who in the judgment of the faculty is best qualified in all departments of medicine, and to Lieut Milton Virshup, M C, who received the Phi Delta Epsilon Prize, awarded for the highest scholastic record Lieutenant Virshup also received the alumni prize awarded to the member of the class best qualified in gynecology Dr Mildred Elsie Kamner received the Dudley Memorial Medal for the best clinical report of a case in the surgical wards of the Long Island College Hospital, and Dr Catherine Elva Spears the prize of the class of 1898 awarded to the student whose scholastic average in the fourth year has shown the greatest improvement over that of previous years Other prize awards went to Dr Louis Jay Scheinman, who received the Ford Prize awarded for the best dissection, Lieut Sam Tully Simpson, M C, the obstetric prize awarded for the best thesis on a subject in obstetrics, and Lieut Bertram E Bromberg (MC), the Joseph Howard Raymond Prize in physiology

NORTH DAKOTA

State Medical Election.—Dr Albert E Spear, Dickinson was named president-elect of the North Dakota State Medical Association at a meeting of the council and house of delegates in Valley City May 20-21, and Dr James F Hanna, Fargo, was inducted into the presidency Vice presidents are Drs Philip G Arzt, Jamestown, and Wilbert A Liebeler, Grand Forks, Dr Leonard W Larson, Bismarck, is secretary and Dr William W Wood, Jamestown, treasurer Dr Aloysius P Nachtwey, Dickinson, was named delegate to the American Medical Association and Dr Willard A Wright, Williston as the alternate Minot was selected as the 1946 convention city

Meeting on Obstetrics—Dr Edwin H Boerth, Buffalo, was elected president of the North Dakota Society of Obstetrics and Gynecology at its semiannual meeting in Fargo May 26 and Dr Paul W Freise, Bismarck, was named vice president Dr Gerald Wilson Hunter, Fargo, was chosen secretary-treasurer Among the speakers at the meeting were

Dr Frederick L Schade, Worthington, Minn, The Rh Factor in Pregnancy
Dr Boerth, Case Report—Erythroblastosis Fetalis
Dr Freise External Version
Dr Russell J Moe, Duluth, Minn, Amnion Fluid Embolism
Dr William F Mercil, Crookston, Minn, Case Report—Postpartum Mesenteric Thrombosis
Dr Robert B Woodhull Minot, Radium in Menopausal Bleeding
Dr Claude J Ehrenberg, Minneapolis, The Prepartum and Intrapartum Use of Ergot

OHIO

Academy of Medicine Seeks Funds—The Toledo Academy of Medicine is in the midst of a campaign to raise funds either to modernize the present academy building or to build a new one, depending on the amount of money subscribed, according to the *Ohio State Medical Journal*

Physician Sentenced in Narcotic Racket.—Dr Erich Otten, Akron, who was arrested recently on a charge (THE JOURNAL, May 19, p 217), was sentenced July 9 to a year and a day's imprisonment by U S District Judge Emerich B Freed, according to the Cleveland *Press* The physician was said to be one of a group involved in a $100 000 a year 'dope racket in the Akron area which was exposed by federal narcotic agents The *Press* stated that the physician had been supplying narcotics to about 150 drug addicts before his arrest

Personal—Dr Harry L Rockwood, for fifteen years superintendent of Mount Sinai Hospital, Cleveland, has resigned to take over the newly created position of medical director of the Cleveland city infirmary and chronic disease hospital Warrensville William B Seltzer, superintendent of Bronx Hospital, New York, since 1930, is the new superintendent at Mount Sinai——Dr Robert D Taylor, Indianapolis, has joined the research division of the Cleveland Clinic Foundation effective July 1——Dr Joseph B Stocklen Cleveland, is the new president of the Ohio Public Health Association——Dr James P Parlante, Shadyside, has been appointed medical director of the Powhatan Mining Company, Powhatan Point to succeed Dr James M Skinner Jr, effective July 1 Dr Skinner who held the position for the past fourteen years resigned to enter private practice in New Martinsville, W Va——Dr Richard B Holt, U S Public Health Service has been named head of the U S Marine Hospital, Cleveland succeeding Dr Alvin R Sweeney (THE JOURNAL, July 21 p 891)——Dr Charles E Holzer, Gallipolis who received the honorary degree of doctor of laws from Ohio State University, Columbus, recently was cited as 'an outstanding citizen devoted to public service, an organizer and promoter of productive enterprises of economic and social importance'

OKLAHOMA

State Association Honors Governor.—The Oklahoma State Medical Association held a banquet recently in honor of Governor Robert S. Kerr in appreciation of his interest in the health of the people of the state. Other guests included members of the twentieth legislature, all of whom were helpful in the passage of various health bills. Dr. Tom Lowry, dean of the University of Oklahoma School of Medicine, was toastmaster. Speakers included the governor, members of the legislature and representatives of the state health department, the medical school and the state medical association.

OREGON

Personal.—Dr. Carl G. Heller, assistant professor of physiology, Wayne University College of Medicine, Detroit, has been appointed associate professor of physiology and medicine at the University of Oregon Medical School, Portland.——Dr. William H. Earl has been named health officer of Cottage Grove, succeeding the late Dr. Albert W. Kime.

Kenneth Swan Named Professor of Ophthalmology.—Dr. Kenneth C. Swan, associate professor, has been appointed professor and head of the department of ophthalmology at the University of Oregon Medical School, Portland. He is succeeding Dr. Frederick A. Kiehle, who has been named professor emeritus. Dr. Kiehle has been associated with the school since 1910.

TEXAS

Medical College Honored with Anniversary Issue.—The *Dallas Medical Journal* for June was designated a special anniversary edition to commemorate the second anniversary of the Southwestern Medical College. The journal contains editorial comments and the history of the various departments of the school.

University News.—Charles M. Pomerat, Ph.D., professor of anatomy, University of Texas Medical Branch, Galveston, is a guest worker on invitation for a month at the Institute de Salubridad Enfermidades Tropicales, Mexico City, D. F. Dr. Pomerat will work on tissue culture experiments with reference to retiçuloendothelial immune serums.——Dr. Heinrich W. Neidhardt of the department of pathology, University of Kansas School of Medicine, has been appointed assistant professor of pathology at the university, effective August 1.——Wilbur A. Selle, Ph.D., professor of physiology, is a guest research worker for several months at the Massachusetts Institute of Technology, Cambridge, on problems in physical medicine, under the auspices of the Baruch Committee on Physical Medicine.——MacDonald Fulton, Ph.D., formerly professor of bacteriology, Southwestern Medical College, Dallas, has been appointed visiting professor of pediatrics research at the university. He will be in charge of bacteriologic studies relating to Salmonella organisms as part of the child health program supported by the William Buchanan Foundation, Texarkana.——The Smith, Kline & French Laboratory, Philadelphia, has made a grant to the pharmacology laboratory of the university for a study of the influence of the reticuloendothelial system in trypanosomiasis and syphilis. Paul L. Ewing, Ph.D., associate professor of pharmacology, will have charge of the research effort and will conduct certain studies under the direction of Dr. Arthur L. Tatum, professor of pharmacology, University of Wisconsin Medical School, Madison.

VERMONT

New Dean at University of Vermont.—Dr. William Eustis Brown, associate professor of preventive medicine, University of Cincinnati College of Medicine, has been appointed full time dean of the University of Vermont College of Medicine, Burlington, effective September 1. Dr. Clarence H. Beecher, who has been serving as dean on a part time basis, will continue to serve the school as professor of medicine.

WASHINGTON

Changes in State Health Department.—Dr. Rollin E. Cutts has been appointed head of the maternal and child hygiene and crippled children's section of the Washington State Department of Health. Dr. Cedric Northrop has been named in charge of the newly created section of tuberculosis control. Howard W. Lundy, Dr.P.H., has been appointed head of the section on public health education.

Personal.—Dr. and Mrs. George W. Ingham, Olympia, observed their fiftieth wedding anniversary, April 17.——Dr. Robert H. Welding, Ellensburg, has resigned as health officer of Kittitas County. L. H. Walker, D.O., health officer of Ellensburg, has been named to succeed Dr. Welding.——Dr. Paul A. Lindquist has been appointed health officer of Walla Walla County. He succeeds Dr. Arthur L. Ringle, who recently became state health commissioner with offices in Seattle.

WEST VIRGINIA

Scholarships in Public Health.—The West Virginia Health Department has announced that four scholarships in public health will be offered successful applicants, who will receive nine months' postgraduate training at the School of Public Health at the University of North Carolina, leading to a degree of master of public health education. Field training for a period of three months will follow, during which applicants will receive a monthly stipend of $100. Full travel expenses will be allowed during the period of field training. Applicants must be college graduates, and scholarships will be awarded to those who evince a sincere desire to make public health their career. Many positions as public health educators are now available as a result of the rapid expansion in the field of public health in the state.

New Procedure in Application for Cancer Treatment.—Needy cancer patients may now apply for treatment and care through county, district and city health departments under a new setup announced by Dr. Paul R. Gerhardt, director of the West Virginia state division of cancer control. The new procedure follows the recommendations of the public health council and the cancer committee of the West Virginia State Medical Association that further case referral sources be developed. Heretofore all applicants had been referred through the county department of public assistance. Evidence must be submitted to show that there has been a diagnosis of cancer and that the patient is unable to pay for treatment and care. One of the new forms to be used in submitting the information must be signed by the applicant and the referring agency and must be filled out by the city, county or district public health officer or public health nurse. Applications for care may also be filed with the local department of public assistance. The second form, which is a medical report of the case, is to be filled out by the patient's physician without charge to the division. Both forms should be sent to the division of cancer control, 1719 East Washington Street, Charleston, since no disposition of a case can be made until both types of information have been received on form CA-1 and form CA-2. The division will notify the patient whether the application can be accepted and where to report for treatment. A copy of the notice will be sent to the referring agency. A patient will be referred to the nearest of twelve treatment centers in the state. The division of cancer control cannot pay transportation cost, and local resources should be utilized if the patient or the family is unable to assume responsibility.

WYOMING

State Medical Election.—Dr. William A. Steffen, Sheridan, was recently chosen president-elect of the Wyoming State Medical Society and Dr. William Andrew Bunten, Cheyenne, was installed as president. Other officers include Drs. Thomas J. Riach, Casper, vice president; Peter M. Schunk, Sheridan, treasurer; George E. Baker, Casper, secretary, and George P. Johnston, Cheyenne, delegate to the American Medical Association.

Personal.—Dr. Edwin Earl Whedon, Sheridan, has been appointed a member of the state board of health.——Drs. George H. Phelps, Cheyenne, Junius C. McHenry, Gillette, Roscoe H. Reeve, Capper, and Foster G. Shaffer, Douglas, have been appointed to the Wyoming State Board of Medical Examiners.——Dr. George P. Johnston, Cheyenne, who observed his eighty-second birthday recently, is, according to the *Rocky Mountain Medical Journal*, the oldest practicing physician in Wyoming.

ALASKA

New Commissioner of Health of Alaska.—Dr. Conrad Earl Albrecht was recently placed on inactive status in the Army to become commissioner of health for the Territory of Alaska, effective July 1. Dr. Albrecht, who graduated at Jefferson Medical College of Philadelphia in 1932, reports that members of the new board of health are Dr. Dwight L. Cramer, Ketchikan; Mrs. Katherine Kehoe, Nome; Rev. R. Rolland Armstrong, Anchorage, and Mr. George Preston Sr.,

Fairbanks (THE JOURNAL, June 2, p. 379). Dr. George A. Hays has been executive director of the Territorial Department of Health since his loan from the U. S. Public Health Service in the fall of 1942. *Northwest Medicine* credits Dr. Hays with accomplishing numerous medical improvements in Alaska during his service. The 150 bed hospital at Skagway belonging to the Northwest Service Command and valued at about one million dollars was turned over to the territory without cost through Dr. Hays' efforts. The hospital is now functioning for white persons as well as for natives, and the Alaska Office for Indian Affairs has made an appropriation of $200,000 to assist in the work.

PHILIPPINE ISLANDS

Meetings of Ophthalmologists.—The first meeting since the Japanese occupation of Manila of civilian and military physicians interested in diseases of the eye, ear, nose and throat was held in the chapel of the Philippine General Hospital, Manila, July 5. The meeting was arranged by Dr. Herminio Velarde, assisted by Dr. Herminio Velarde Jr. and Dr. Antonio G. Sison, dean of the University of the Philippines College of Medicine and director of the hospital. Most of the patients presented were civilians suffering from malnutrition, tuberculosis, yaws, war injuries and wasting diseases. Although the medical school is completely damaged, the staff of the hospital is managing to treat several thousand patients with the barest equipment and little laboratory assistance. On July 26 all medical officers in the area were invited to attend a clinical conference at the San Lazaro Hospital, Manila. The meeting featured eye, ear, nose and throat cases of leprosy, yaws, tuberculosis and contagious diseases under the auspices of the staff of the hospital.

GENERAL

Anton Carlson Made Director of Alcohol Council.—Dr. Anton J. Carlson, emeritus professor of physiology, University of Chicago School of Medicine, has been appointed on a part time basis as director of the Research Council on Problems of Alcohol, New York.

Congress of Ophthalmology.—The Pan American Congress of Ophthalmology will definitely take place in Montevideo, Uruguay, the week of November 26. A comprehensive program will be presented, which will include reports from two committees, namely that on the prevention of blindness and that on trachoma. From these committee reports it is hoped that some codification will eventuate in uniformity throughout the entire Western Hemisphere. Despite wartime restrictions, it is still possible for a limited number of North American ophthalmologists to obtain transportation to Montevideo. Arrangements can be made through the American Express Company and the Pan American Airways.

Two Years' Study of Military Educational Technics.—The American Council on Education has received a grant of $150,000 from the Carnegie Corporation of New York and the General Education Board to carry on a two year investigation to determine what civilian schools and colleges can learn from Army and Navy wartime educational technics. The study will be under the direction of Alonzo G. Grace, Ph.D., commissioner of education of Connecticut, on leave of absence for the purpose. Dr. Grace will establish headquarters and staff in Washington and will also have the assistance of a special commission of leading educators, who will meet with the staff from time to time and visit military and naval installations to observe training programs in operation. Included in the comprehensive study of educational needs will be the consideration of training programs for leadership and for the training of teachers in physical education and health.

Gallup Poll on Cancer.—The American public would favor a congressional appropriation of a $200,000,000 fund for the study and treatment of cancer, according to a Gallup poll published in the newspapers July 21. Three out of four persons said they were willing to pay more taxes to provide the money. In reply to a question issued by the American Institute of Public Opinion, "Should Congress pass a law which would provide $200,000,000 for the study and treatment of cancer in this country?" "Yes" was returned in 81 per cent, "no" 10 per cent and "no opinion" in 9 per cent. For the question "Would you be willing to pay more taxes to provide this money?" 75 per cent voted "yes," 20 per cent "no" and 5 per cent "no opinion." The newspaper report stated that the studies by the institute have shown that the American public still has many misconceptions and false notions about cancer, indicating the need for continuous educational campaigns.

Association of Medical Illustrators.—Mr. Tom Jones, professor of medical and dental illustration, University of Illinois Colleges of Medicine, Dentistry and Pharmacy, Chicago, was elected president of the Association of Medical Illustrators at its organization meeting in Chicago, July 16-19. Other officers include Mr. Willard C. Shepard, art editor, W. B. Saunders, publishing company, Philadelphia, vice president; Muriel McLatchie, Massachusetts General Hospital, Boston, secretary, and Elizabeth Brödel, New York, treasurer. The association was formed to promote the study and to encourage the advancement of medical illustration and allied fields of visual education to promote understanding and cooperation with the medical and dental professions, including public health and nursing and to advance medical education. The association begins with a charter membership of about fifty-four, and Philadelphia was tentatively selected as the site for a meeting in 1946. A dinner honoring the delegates to the organization meeting was given July 17 (THE JOURNAL, July 7, page 744). The association will include members in Latin America and Canada.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended July 21 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Division and State	Week Ended 7/21, 1945	Week Ended 7/22, 1944

Narcotic Violations.—The U. S. Bureau of Narcotics announces the following actions:

Dr. James E. Sherman, Houston, Texas, pleaded guilty in the U. S. District Court at Houston, May 4, to violation of the federal narcotic law and was sentenced on count 1 to serve a term of two years in jail; on count 3 the sentence of one year and one day was suspended and he was placed on probation for a period of five years, which is to take effect on the expiration of the two year sentence received for count 1. Count 2 was dismissed.

Dr. Robert E. Heath, Uniontown, Pa., pleaded guilty on June 8 in the U. S. District Court in Erie, Pa., to violation of the federal narcotic law. His sentence of two years was suspended and he was placed on probation for a similar period; he was also ordered to pay the cost of the criminal proceedings.

Dr. Ralph S. Walter, Harrisburg, Pa., pleaded guilty in the U. S. District Court in Harrisburg, May 8, to violation of the federal narcotic law. He was fined $300 and placed on probation for one year.

Dr. Wayne D. Daugherty, Grove City, Pa., on March 21 pleaded guilty in the U. S. District Court to violation of the federal narcotic law. He was given a two year suspended sentence and placed on probation for a similar period; he was also ordered to pay the costs of prosecution.

Dr. Weir M. Hamilton, Natrona, Pa., on April 25 pleaded guilty in the U. S. District Court at Erie. He was given a suspended sentence of five years and placed on probation for a similar period. The court further stipulated that the physician enter the U. S. Public Health Service Hospital at Lexington, Ky., for treatment of his addiction to narcotics and remain there until discharged by the authorities.

Dr. Herbert L. Wright, Konawa, Okla., on May 21 pleaded guilty in the U. S. District Court at Muskogee, Okla., to violation of the federal narcotic law. He was given a suspended sentence of five years and placed on probation for a similar period.

Dr. Samuel H. Dender, New York, convicted in the Southern District Court of New York of violation of the federal narcotic law, on March 21 was sentenced to a term of two years and fined $1,500 on four counts of the indictment. On the remaining counts of an indictment sentence was suspended, and he was placed on probation for a period of one day to begin at the expiration of the penitentiary sentence on condition that he resign from the medical profession. The state board of medical examiners voted on April 20 to revoke Dr. Dender's license to practice medicine in New York.

Dr. Charles H. Hamilton, Vermont, Ill., pleaded guilty July 5 to violation of the federal narcotic law. His sentence was suspended and he was placed on probation for a period of two years and ordered to pay a sum of $50 for costs.

Central Medical War Committee of British Medical Association Thanked by the Government for Its Services

On the termination of the war in Europe Mr. Willink, minister of health, has thanked the Central Medical War Committee of the British Medical Association for its valuable help and cooperation during the past six years. He says that its task, readily undertaken at the outbreak of war, assumed a magnitude and complexity greater than could have been foreseen, but its members shouldered the work with determination and efficiency. Their first duty was to provide the practitioners necessary for the medical needs of the armed forces. This was indeed a positive contribution to victory. He knew the difficulties of weighing the counterclaims of civilian needs in general practice, hospitals, public services, teaching, research and other fields. As the war lengthened and civilian medical resources were progressively deleted, almost each individual case became a problem, but the committee could always be relied on for a sound and fair minded judgment in striking the balance between civil and military needs. It also gave much careful consideration to safeguarding the interests of serving practitioners.

The Urinary Complications of Pregnancy

At a joint meeting of the Sections of Urology and of Obstetrics and Gynecology of the Royal Society of Medicine Mr. Joel Gabe opened a discussion on the urinary complications of pregnancy. He described the changes which occurred in the urinary tract during pregnancy. As early as the third month there were changes in the upper urinary tract. The anatomic changes most often seen were dilatation of the calices, pelvis and ureter as far down as the pelvic brim. The abdominal ureter was often elongated and might become tortuous, kinked and laterally displaced. Kinking usually affected the upper third of the ureter and there might be so much as to obstruct ureteral catheters. Even before the uterus was large enough to exert pressure certain physiologic changes—atony, relaxation and stasis—occurred. These were generally regarded as due to the action of hormones elaborated by the placenta. If the urine of pregnant women was injected into virgin rabbits, changes were produced in their urinary tracts like those observed in the pregnant animal. It had also been shown that the amount of the luteinizing principle and estrogen excreted in the urine increased during pregnancy.

The stasis and atony which occurred in the urinary tract were the perfect prerequisites for infection and it was remarkable that this did not more often happen. Stasis was found in 73 per cent of primiparas and in 45 per cent of multiparas. When excessive it might cause temporary renal impairment, but normally the total renal function was unaffected, and there were no changes in the blood chemistry. After normal pregnancy retrogressive changes occurred in 60 per cent of women within two weeks of delivery and intravenous pyelograms were usually normal by the tenth day of the puerperium. Ureteral atony might last for a fortnight or longer.

Miss Gladys Dodds discussed 287 cases of antepartum pyelitis admitted to University College Hospital. The average age was 25.4 years and 185 were primiparas. The infection occurred most commonly before the twenty-fifth week. The onset in the majority was sudden, with acute stabbing pain referred to one side, often associated with shivering, occasionally with frequency of micturition and less often with vomiting. The acute stage lasted on the average six days and then the general condition improved. In just over 10 per cent the course was more unfavorable, the temperature remaining high, the general condition not improving, and anemia perhaps developing as a result of the prolonged sepsis. Two patients died after the pregnancy terminated, 1 after spontaneous labor in the twenty-ninth week, the other nine days after hysterotomy at the twenty-third week. Necropsies showed in 1 case mild pyelonephritis and in the other pyelonephritis with the acute inflammation of the kidney pelvis and ureters.

The early patients, numbering 186, were treated with large doses of alkalis, occasionally with acids and methenamine. Only 4 so treated had sterile urine during the pregnancy. Another group of 37 were treated by a ketogenic diet or by mandelic acid. Five had sterile urine after treatment. A third group of 64 were treated with sulfonamides and in 36 the urine became sterile. Of the total number, 236 were subsequently delivered in a hospital of a viable fetus. Signs of toxemia developed in 73 before the end of pregnancy and 2 had eclampsia. The incidence of toxemia was thus 30.9 per cent, which was lower than that of the normal clinic population.

Cold Storage of Skin for Autogenous Grafting

The severe burns sustained in airplane crashes often necessitate a succession of operations for which the patient is unsuited mentally and physically. In a Hunterian lecture, delivered at the Royal College of Surgeons, Squadron Leader D. N. Matthews, medical officer in charge of a plastic unit of the Royal Air Force, described a method by which the number of operations could be reduced and which had other uses. A succession of operations had been necessary because the time required to surface all the areas at one operation was prohibitive and because the operation would have to be postponed until all the sloughs had separated and all the areas were bacteriologically clean enough for skin grafting. This would mean that the areas ready first would have to wait until the slower areas were also ready; during this time fibrosis would progress and the functional and cosmetic would therefore suffer. The method of Matthews reduces the number of operations to the short one necessary for cutting the skin. The stored skin can then be applied as a bedside dressing without anesthesia, as and when required.

Skin storage has other uses. It reduces the number of donor areas necessary in multiple stage routine plastic repair of healed wounds. The patient is saved the pain of a second or even a third donor area. The duration of each operation after the first is also lessened by the time it would have taken to cut a fresh graft. Another use is to provide a spare piece of skin in case the graft partially fails. Finally, stored skin provides an experimental skin bank for investigating the problems of heterogenous grafting.

Matthews preserves skin by folding it with its raw surfaces opposed and wrapping it in a piece of tulle-gras, and this in turn in a piece of gauze wrung out of isotonic solution of sodium chloride. It is then put in a sterile, air tight, screw stopped glass bottle and held away from the small amount of fluid which collects in the bottle by insertion of a rubber ring or leadfoil to rest on. The bottle was stored in a household refrigerator at a temperature between 3 and 6 C. At this low temperature the autolytic activity of the tissue enzymes and the destructive power of microbes are slowed. The cells pass into a state of latent or suspended life. Grafts which had been stored for periods up to twenty-one days took satisfactorily in all cases when applied to granulating surfaces. Successful grafting after cold storage was described by the French surgeon de Martigny in 1913. Carrel in 1912, when discussing tissue culture of pieces of skin, stated that when they ceased to proliferate he placed them in cold storage for several days "in a state of latent life" and then, when he replaced them in a

suitable medium, he observed new and active growth. Thus the principle of cold storage of skin for grafting is not new, but its application by Matthews in the treatment of the burns of airmen is an innovation.

BUENOS AIRES

(From Our Regular Correspondent)

June 15, 1945.

Surgical Therapy of Arterial Hypertension

At a recent meeting of the Society of Internal Medicine of Buenos Aires at which Dr. Egidio S. Mazzei presided, surgical therapy of arterial hypertension was the subject of discussion. Dr. Anibal S. Introzzi of Buenos Aires said that arterial hypertension and its complications are the causes either of death or of permanent invalidism of a large number of relatively young persons. Death of persons over 50 is due to arterial hypertension in 25 per cent of the cases. Many patients cannot afford the necessary rest. Drs. Julio Palacio, G. Hugo Dickmann, Egidio S. Mazzei and Andres A. Veppo reported observations in 17 cases of hypertension. Surgical therapy is indicated in certain cases after failure of medical therapy. Smithwick's operation is indicated (1) when hypertension does not diminish after a period of mental and physical rest of the patient during which the proper diet and proper therapy are administered, (2) when headache, anxiety and irritability are either acute or almost constant, (3) when cardiac accidents (cardiac asthma, pulmonary edema and acute waves of hypertension) are menacing the patient and (4) in cases either of vascular spasm or of papillary edema of the fourth type and hypertension of Keith and Wagener's type and also when renal insufficiency is still subacute. Proper therapy consists of iodides, antispasmodics and vasodilating drugs. Acute renal insufficiency, subacute retinal arteriosclerosis which shows hypertension of either acute or long course, cardiac insufficiency and angina pectoris contraindicated an operation on patients with hypertension.

Dr. Benito Just Tiscornia discussed the pathognomonic and nonpathognomonic ocular signs of arterial hypertension before and after surgical therapy. Papillary and retinal edema, congestion of the macula, exudates and hemorrhages may diminish or else disappear after the operation. Organic lesions, arteriovenous anastomosis, arteriosclerosis and the hypertensive aspect of the blood vessels are not modified after the operation. The changes in the fundus of the eye showing improvement depend on the degree of favorable changes of arterial pressure. The visual acuity and clear perception of objects improves in all cases after the proper surgical therapy of hypertension. The operation should be performed during the first or second states in the course of hypertension (according to Keith and Wagener's classification). In these second stages of the disease the operation prevents the occurrence of secondary changes of the fundus of the eye. However, even in the third and fourth stages of the disease the operation gives good results in hypertension.

Social Medical Centers

The National Department of Public Health of Argentina recently passed regulations compelling mutual insurance associations and organizations of a medicosocial type to declare the type of work they carry on and the bases on which the medicosocial service is given the insured. The National Department of Public Health can approve or cause modifications in the conduct of such centers.

New Hospitals in Countries of Latin America

More than one hundred hospitals, dispensaries and public health centers have been recently organized in Latin American countries under the auspices of the Office of Inter-American Affairs. Twenty-four of these were opened in Brazil, Bolivia, Peru and Colombia. New hospitals and dispensaries are already functioning or will soon function in Lima, La Paz and several mine regions of Bolivia. A leprosarium was recently opened in São Paulo. The efforts of four hospitals and of twenty-four health centers in Central America are directed toward the control of malaria and the teaching of public health. Several of these centers are situated along the Pan American road, others are located in territories in which rubber or textiles are produced. The construction and functioning of health centers in Uruguay are under the direction of the Inter-American Cooperative Center of Public Health. The main activity of these centers is concerned with various phases of preventive medicine.

Reappointment of Professors of Universities

In October 1943 several professors of the Universities of Buenos Aires, La Plata, Litoral, Cordoba and Tucumán issued a manifesto proclaiming their democratic ideals. The government removed the professors from their chairs. Members of the government asked the universities to normalize their functions. The professors were requested to return to their chairs. Dr. B. A Houssay was the last to accept reinstatement in the Faculty of Buenos Aires. The request for his reinstatement was made by the faculty and the government. The professors signed reinstatement papers on the condition of the maintenance of academic freedom and their attitude toward democracy.

Medical Society at Rio de la Plata

The Sociedad de Medicina Interna of Rio de la Plata was recently established. It will function in collaboration with the Societies of Internal Medicine of Buenos Aires and of Montevideo. Drs. Egidio S. Mazzei of Buenos Aires and Héctor Franchi of Montevideo are the presidents.

Brief Items

A committee for moral help to the blinded in war was recently established in Buenos Aires.

Dr. Egidio S. Mazzei of Buenos Aires, ex-president of the Society of Internal Medicine of Buenos Aires, was appointed regular professor of clinical medicine at the Faculty of Medicine of the University of La Plata.

Deaths

Dr. Alejandro A. Raimondi, aged 67, head of the Hospital Tornú of Buenos Aires, died on Feb. 11, 1945.

Marriages

FLOYD SAMUEL BARRINGLR, Emden, Ill., to Miss Winifred Lois Wain of Forest Hills, N. Y., in Ripley, England, June 2.

JOSEPH J. LIKOS, Los Angeles, to Miss Lorraine Martha Rolle of East St. Louis, Ill., in St. Louis, June 15.

BRUCE D. LEE, River Forest, Ill., to Ensign Jane Roberts of Pocatello, Idaho, in Washington, D. C., April 20.

BENJAMIN JACKSON PHILIPS JR., Jacksonville, Fla., to Miss Carolyn Parker of Lenoir, N. C., June 24.

HENRY DONATO, Mount Pleasant, S. C., to Miss Anne Theodore Koster of Charleston, June 19.

JAMES RAY NUNEZ, Abbeville, La., to Miss Agnes Pietrowski of Jersey City, N. J., June 2.

WARD JOHN MCFARLAND, Glenbrook, Conn., to Miss Mary Luise Henry in Orange, June 23.

ROBERT CHARLES HASTY, Omaha, to Miss Jeanetta Jane Bryant of Norfolk, Va., June 4.

HUGH MCCULLOCH JR., St. Louis, to Miss Patricia Rentsler of Plainfield, N. J., June 24.

ARTHUR M. PARKER, Brookline, Mass., to Miss Sheryl Newiger of Brooklyn, July 1.

CARL DOUGLAS HUCKLEBERRY, Danville, Ind., to Miss Marcia Connor of Sullivan in June.

ARTHUR A. GOLDFARB to Miss June Florence Wax, both of New York, June 3.

Deaths

Isaac Levin ⊕ New York; University of Tomsk Faculty of Medicine, Russia, 1890; interned at the Military Medical Academy in St. Petersburg, Russia; attending surgeon at the Army Hospital in St. Petersburg, Russia, 1890-1891; associate in pathology at Columbia University from 1909 to 1912 and associate in cancer research from 1912 to 1915; for many years clinical professor of cancer research at the University and Bellevue Hospital Medical College; specialist certified by the American Board of Radiology, Inc.; member of the American Association of Pathologists and Bacteriologists, Harvey Society, American Physiological Society, American Genetic Association, American Association for Cancer Research, Radiological Society of North America, American College of Radiology, Society for Experimental Biology and Medicine and the American Radium Society; fellow of the American Association for the Advancement of Science and the New York Academy of Medicine; director of the New York City Cancer Institute from 1923 to 1930; at various times on the staffs of the Sydenham, Beth David, Montefiore, St. Bartholomew's and Lebanon hospitals; editor of *Archives of Clinical Cancer Research* from 1925 to 1930; died June 19, aged 78.

Lee Maidment Hurd ⊕ Rowayton, Conn.; Columbia University College of Physicians and Surgeons, New York, 1895; professor emeritus of laryngology at the New York University College of Medicine and professor of otolaryngology at the New York Polyclinic Medical School and Hospital, New York; an Affiliate Fellow of the American Medical Association; retired member of the Medical Society of the State of New York; member of the American Academy of Ophthalmology and Otolaryngology and American Laryngological Association; member and past president, American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; consulting laryngologist at the Downtown Hospital, New York; attending otolaryngologist at the New York Polyclinic Medical School and Hospital, New York, where he died May 15, aged 71, of arteriosclerotic heart disease and parkinsonism.

Frederick William Shaw, Richmond, Va.; University of Kansas School of Medicine, Kansas City, 1906; research professor of bacteriology at the Medical College of Virginia, where he had been professor of bacteriology and parasitology and head of the department, professor of bacteriology and clinical pathology and associate professor of bacteriology; associate professor and professor of hygiene at the University of Missouri School of Mines from 1919 to 1924; member of the American Society of Clinical Pathologists, Richmond Academy of Medicine and the American Medical Association; at one time associated with the Indian Service; major, medical corps, U. S. Army, 1917-1918; formerly physician at State Hospital number 1 in Fulton, Mo.; died in the Medical College of Virginia Hospital May 29, aged 62, of gastric ulcer.

Lawrence George Hanley, Buffalo; Niagara University Medical Department, Buffalo, 1887; member of the American Medical Association; served on the faculties at his alma mater and the University of Buffalo School of Medicine; an examiner for the city civil service commission; for many years on the surgical staff of the Buffalo Hospital of the Sisters of Charity, serving as its president; on the staffs of the Emergency Hospital, St. Mary's Infant Asylum and Maternity Hospital, Our Lady of Victory Hospital and Providence Retreat; said to be the first ambulance surgeon in the city of Buffalo; awarded the honorary degree of doctor of laws from Niagara University in 1912; died May 22, aged 81, of myocardial failure.

Charles Leo Merrill, Salina, Utah; University of Illinois College of Medicine, Chicago, 1920; member of the American Medical Association; in 1942 chosen honorary president of the Utah State Medical Association; served during World War I; at one time professor at the Utah State Agricultural College, Logan; later spent three years in South America with the U. S. Extension Division of the Agricultural Department; twice mayor of Salina; medical superintendent and owner of the Salina Hospital; died in the Dr. W. H. Groves Latter-Day Saints Hospital, Salt Lake City, May 25, aged 57, of coronary thrombosis.

Gertrude Allen, Hackettstown, N. J.; New York Medical College and Hospital for Women, Homeopathic, New York, 1890; died in Bloomfield May 29, aged 79, of cardiac degeneration.

Marcus Moses Anshin ⊕ Lynn, Mass.; Loyola University School of Medicine, Chicago, 1919; on the courtesy staff of the Lynn Hospital; died in the New England Deaconess Hospital, Boston, May 21, aged 52, of myocarditis.

George Ballantyne Brown, Oakland, Calif.; College of Physicians and Surgeons of San Francisco, 1918; member of the American Medical Association; died March 1, aged 52, of rupture of the heart.

Bascomb Lanier Chipley ⊕ Chillicothe, Ohio; University of Maryland School of Medicine, Baltimore, 1906; member of the American Society of Anesthetists, Inc.; fellow of the American College of Chest Physicians; superintendent of the Mount Logan Sanatorium; on the staff of Chillicothe Hospital; member of the board of directors of the Ross County Tuberculosis Association; died in Brunswick, Md., May 13, aged 61, of heart disease.

William H. Cooper, Catchings, Miss.; Mississippi Medical College, Meridian, 1910; died May 13, aged 67.

Charles Morgan Davis, Laurel, Miss.; University of Nashville (Tenn.) Medical Department, 1890; Vanderbilt University School of Medicine, Nashville, 1890; member of the American Medical Association; died May 22, aged 76.

William Thompson DeCoster, Mankato, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1897; died March 26, aged 70, of coronary thrombosis.

Arthur Charles Delacroix, Bernardsville, N. J.; University of the City of New York Medical Department, New York, 1892; member of the American Psychiatric Association; died in the Memorial Hospital, Morristown, May 7, aged 74, of arteriosclerosis and cardiac decompensation.

Peter Lycourgou Economos, Detroit; National University of Athens School of Medicine, Greece, 1897; died in the Harper Hospital May 15, aged 69, of adenocarcinoma of the pancreas.

Frank Alvin Elders, De Soto, Mo.; Bennett Medical College, Chicago, 1915; served in the medical corps of the U. S. Army in France during World War I; died in Hot Springs National Park, Ark., May 25, aged 56, of coronary disease.

Robert Trimble Foster, Groom, Texas; Atlanta School of Medicine, 1906; honorary member of the State Medical Association of Texas; member of the American Medical Association; served as local surgeon for the Rock Island Railroad; died March 27, aged 61, of heart disease.

John McIver Furman ⊕ Fort Worth, Texas; Memphis (Tenn.) Hospital Medical College, 1902; president of the Tarrant County Medical Society in 1939; died March 21, aged 73, of coronary occlusion.

Samuel Sampson Glasscock, Goodland, Kan.; Rush Medical College, Chicago, 1887; member of the American Medical Association; honorary member of the Kansas Medical Society; at one time professor of psychiatry at the University of Kansas School of Medicine in Kansas City, where he was medical director of the Grandview Sanitarium and on the staff of the Bethany Hospital; formerly assistant medical director of the State Sanatorium for Tuberculosis in Norton; died April 28, aged 83, of coronary thrombosis.

Edward Cornelius Haagensen ⊕ Grand Forks, N. D.; Northwestern University Medical School, Chicago, 1894; served as city health officer; on the staffs of the Grand Forks Deaconess and St. Michael's hospitals; died in a local hospital March 28, aged 75, of heart disease.

Austin Hutchison ⊕ Bixby, Okla. (licensed in Oklahoma under the Act of 1908); on the courtesy staff of the Hillcrest Hospital in Tulsa; local surgeon for the Mid-Valley Railway Company; died March 27, aged 70, of coronary occlusion.

Gordon H. Jackson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; died in the Presbyterian Hospital March 9, aged 58, of heart disease and arteriosclerosis.

Darie Lemieux ⊕ Rolla, N. D. (licensed in North Dakota in 1900); in 1905 member of the state house of representatives; for four years mayor of Dunseith; acting assistant surgeon of the U. S. Public Health Service during World War I; a member of the state tuberculosis board of trustees; for many years superintendent of the Rolette County Board of Health; died in St. Andrews Hospital, Bottineau, March 26, aged 70, of pleurisy.

George Lafayette Lewis ⊕ San Angelo, Texas; University of Texas School of Medicine, Galveston, 1906; past president of the Fourth District Medical Society and the Tom Green-Coke-Crockett-Concho-Irion-Sterling-Sutton-Schleicher Counties Medical Society; founder member of the San Angelo Medical and Surgical Clinic; on the staffs of St. John's Hospital and the Shannon Hospital, where he died April 5, aged 63, of coronary occlusion.

John William Macune, Ballinger, Texas; Southern Methodist University Medical Department, Dallas, 1913; member of the American Medical Association; president of the Runnels County Medical Society in 1942; for many years city and county health officer; served during World War I; died April 3, aged 63, of lymphosarcoma.

Joseph Samuel McCreary, *Buffalo, Texas;* Baylor University College of Medicine, Dallas, 1932; member of the American Medical Association; interned at the Parkland Hospital in Dallas; began active duty as a captain in the medical corps, Army of the United States, in July 1942; went overseas with the Ninety-Third Division in March 1943, serving in the North African, Sicilian and Italian campaigns; relieved from active duty in October 1944; died February 15, aged 45, of heart disease.

Harvey Lafayette Meador, Clayton, Mo; National University of Arts and Sciences Medical Department, St. Louis, 1913; member of the American Medical Association; health commissioner of Clayton; at one time alderman; on the staffs of the Missouri Baptist Hospital, St. Mary's Hospital and the Deaconess Hospital, St. Louis, where he died April 26, aged 62, of hypertension and arteriosclerosis.

J. M. P. Pichette, Lake Linden, Mich.; School of Medicine and Surgery of Montreal, Que., Canada, 1892; served as health officer of the town of Lake Linden; died May 23, aged 75.

Benjamin Ashby Pope, Newsoms, Va.; Medical College of Virginia, Richmond, 1898; member of the American Medical Association; died in Richmond April 18, aged 69, of cirrhosis of the liver.

Walter V. Prentice, Toledo, Ohio; Toledo Medical College, 1903; in 1932 appointed county jail physician; on the staff of the East Side Hospital, where he died April 30, aged 68, of uremia.

William D. Sears, Ellaville, Ga.; Georgia Eclectic Medical College, Atlanta, 1882; died March 15, aged 88, of acute pyelonephritis

Albert Astor Shelley, Phoenix, Ariz.; Kansas Medical College, Topeka, 1898; member of the American Medical Association, on the staffs of the Santa Monica (Calif.) Hospital, St. Joseph's Hospital and the Good Samaritan Hospital, where he died April 16, aged 78, of dissecting aneurysm of the aorta.

Willard Alvin Stearns, Savannah, Mo.; Lincoln (Neb.) Medical College of Cotner University, 1909; died April 28, aged 76, of coronary sclerosis.

CAPT. RIPLEY BUCKINGHAM
M. C., A. U. S., 1912-1944

CAPT. JOHN WINFIELD BASSETT
M. C., A. U. S., 1913-1943

CAPT. HARVEY RODNEY CLUGSTON
M. C., A. U. S., 1910-1944

Clifford Irwin Oliver ⊕ Graceville, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901 · fellow of the American College of Surgeons; served during World War I; formerly state senator; on the staff of the West Central Minnesota Hospital; died March 27, aged 68, of coronary thrombosis.

Bernard Pehr, John Day, Ore.; Baylor University College of Medicine, Dallas, Texas, 1915; died May 6, aged 70.

Francis Eugene Talty, Hoboken, N. J.; Harvard Medical School, Boston, 1906; member of the American Medical Association and the New England Roentgen Ray Society; died May 27, aged 65.

Rudolf Henry Wald, Los Angeles; Harvard Medical School, Boston, 1904; served overseas during World War I; formerly on the staff of the Charles Miller Hospital in St. Paul; died March 26, aged 71, of arteriosclerotic heart disease.

KILLED IN ACTION

Ripley Buckingham, Washington, D. C.; George Washington University School of Medicine, Washington, 1941; interned at the Garfield Memorial Hospital; entered the medical corps, Army of the United States, on June 11, 1941; began active duty as a first lieutenant in the medical corps on July 1, 1942; later promoted to captain; killed in action in China Aug. 18, 1944, aged 32.

John Winfield Bassett, *San Diego, Calif.;* University of Southern California School of Medicine, Los Angeles, 1940; interned at the Santa Fe Coast Lines Hospital in Los Angeles; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 10, 1939; began active duty in the Army of the United States on Jan. 13, 1941; later promoted to captain; killed in action in the North American area May 29, 1943, aged 29.

Harvey Rodney Clugston, New Orleans; Louisiana State University School of Medicine, New Orleans, 1940; interned at the Charity Hospital in New Orleans; served a residency at the Lafayette Charity Hospital in Lafayette, La.; began six weeks' training period at St. Mary Parish Health Unit at Franklin in March 1942; appointed director of the Red River Parish Health Unit in Coushatta in April 1942, began active duty as a first lieutenant in the medical corps, Army of the United States, on June 13, 1942; later promoted to captain; left for overseas duty in April 1943; died from injuries received in action in Belgium Dec 17, 1944, aged 34.

Correspondence

EARLY HEALING IN CHRONIC OSTEOMYELITIS AND COMPOUND FRACTURES

To the Editor:—Those who are familiar with the surgical program that I have been advocating for many years will remember that I insist on early correct position for inflamed or injured parts, adequate surgical drainage by clean-up of contaminated or inflamed areas (débridement), wide open wounds to provide adequate drainage, prolonged immobilization in correct position, and protection of the wound surface against secondary infection. There must be the same kind of protection (usually by infrequent dressings) until there is sound healing, in the best position for physiologic function in the extremity, and for use of the limb after the patient's recovery.

In dealing with the wound and the wound surface, suturing of the wound should not be done in such a way as to cover up contaminated or septic areas (and thus pockets of infection) during or after wound healing. Efforts at primary and secondary suture, such as are still being advocated, for example, by Dr. Albert J. Key (*Bull. New York Acad. Med.* **21**:87, 1945), have often resulted in immediate flare-ups because of the suturing in of contaminated or infected material or a subsequent explosion with septic complications. Even when such wounds heal primarily, pockets of infection in the scar give trouble later on when they become irritated or traumatized, sometimes long after successful healing is supposed to have taken place.

A new method, which offers not only an opportunity for earlier and sound healing but a satisfactory way of dealing with the wound and wound surface, has been employed recently by Lieut. Ernest M. Burgess, Fort Benjamin Harrison, Billings General Hospital, Indianapolis. Dr. Burgess advocates early skin graft of the wound surface as a new item in my program for osteomyelitis and compound fracture wounds.

The skin graft, when fitted carefully onto the wound surface in such a case, does away with any attempt at suturing and provides the same kind of wound drainage which I have advocated in using the petrolatum pack. The sheet of skin graft not only covers the wound surface and provides wide drainage of the entire cavity but begins the process of healing immediately, so that both drainage and healing go along together in a satisfactory way.

The results already obtained by Lieutenant Burgess indicate that this is so. From my point of view his proposal is entirely rational. It enables the surgeon to carry out the program on which I have always insisted, with the addition that the covering for the wound surface, instead of being a petrolatum pack, under which we must wait for skin growth, is a similar covering but with a pack on top of the graft provided by the surgeon at the time of operation. Under this layer of skin, drainage and healing then go along together, as suggested.

I should recommend also that with the skin graft the use of sulfonamide drugs in the wound be discontinued.

(Since this was written, the following appeared in THE JOURNAL, June 23, p. 598, under the heading "Local Application of Crystalline Sulfonamides Discontinued":)

The War Department Technical Bulletin of Medicine (TB MED 147), March 1945 (distributed to general and field hospitals and other medical units), announced the general policies regarding the local use of chemotherapeutic agents. Experience in wound management justifies the abandonment of local use of any chemical agent in a wound for its supposed antiseptic effect in the prevention or treatment of infection. The practice of routine local application of crystalline sulfonamides to wounds as an emergency aid measure and prior to initial wound surgery will be discontinued. The local application of these compounds to wounds not involving serous cavities following wound surgery will also be discontinued, and their local use in wounds involving serous cavities is not recommended.

This order finally meets a demand I have been making for many years, i. e. that a program of surgical care be substituted for all the attempts to prevent and cure wound infection by chemotherapy. For example: from one of my recent papers, "The Physiologic Factors Involved in Protecting the Patient Against Infection in the Healing of Fractures in Compound Wounds" (*Tr. Coll. Physicians of Philadelphia,* February 1943):

In a recent circular from the Bureau of Medicine and Surgery, Navy Department, April 1942, immobilization of wounds and infected parts is mentioned, débridement and drainage are discussed, but irrigation of wounds is still permitted and reliance for a cure rests chiefly, as far as these official instructions are concerned, upon the sulfa drugs. In eleven pages in the circular on wounds and burns, the sulfa drugs are mentioned on every page, employed for every type of wound and injured part, and in the eleven pages of the circular are mentioned thirty-nine times; ten times oftener than any other drug. The very great danger of poisoning by sulfa drugs is barely referred to.

With so many factors unknown and no possibility of exact determination of the physiologic factors involved we can only infer that whether we breathe germs, swallow them or infect our wounds from the atmosphere we can and usually do defend ourselves against all atmospheric kinds and amounts of infection. And this is true whether the air or we ourselves are treated chemically or not.

As I have pointed out on numerous occasions, my percentage of healing without the use of chemical antiseptics has always been as good as or better than most of the results claimed by others with chemical agents. By doing an adequate drainage, or débridement, by being sure that all pockets are open and then by applying the skin graft over the entire surface, leakage can take place around the skin graft just as it did when I made my first report on this method in 1923, with the petrolatum pack. Suitable provision is made, of course, for the infrequent dressing after-care. Along with this the remainder of our program can of course be carried out; that is, original correct length and position for the inflamed and injured parts, immobilization after operation in plaster of paris, using skeletal pin fixation with plaster of paris when necessary and prolonged protection of the limb, with the patient in the correct position. Perhaps I may be pardoned if I make the observation that, having visited a considerable number of army and navy hospitals during the past two years, I have found that there is excellent technical operative surgery being done, but there has been some disregard of preliminary correction of deformity and inadequate protection of parts in correct position after operation.

Plastic operations are being done on extremities on which no previous attempts at restoration of correct position and function has been attempted, and in the postoperative care immobilization and splinting have been neglected on the theory that early motion is necessary. It is most important to remember that ultimate usefulness depends very largely on anatomic position. The best position possible is necessary in order that inflammatory complications may be avoided and protection of the inflamed or injured parts against damage, even by the patient himself, is most important. For this no apparatus is as good as plaster of paris, properly applied and properly cared for during the entire period of the patient's recovery. Prolonged immobilization is harmful only in those cases in which there is constriction or faulty position or in which infection and inflammatory complication have had inadequate or improper surgical care primarily and secondarily as well.

Meleney of New York has recently reported the results of several years' clinical study of the effects of sulfonamide drugs in wounds (*Surg., Gynec. & Obst.* **80**:263 [March] 1945). He concludes that the sulfonamides have no value in the local prevention or cure of wound infection. For some reason which I cannot understand he thinks that we can find out why sulfonamide drug bacteriostasis is "inactivated" in wounds! And he suggests that we resume the search for a "miracle drug" and fall back on "good surgery," which to many surgeons still means a good operation followed by daily dressings. This is certainly not enough.

H. WINNETT ORR, M.D., Lincoln, Neb.

THE TERM "WHOLE BLOOD"

To the Editor:—Dr. Scannell's contention (THE JOURNAL, June 23, p. 614) that "citrated" blood should not be classified as "whole" blood is erroneous. "Whole" blood means that the blood used for transfusion contains all the vital elements of the blood. Even when a small amount of sodium citrate is added to the blood (0.38 per cent), the blood represents "whole blood." Whether the complicated technic of the stopcock method or similar apparatus (Unger, Soresi, Miller, Scannell, Oehlecker and many others) or the most flexible and simple citrate method is used, the blood represents "whole blood." "Citrated blood" is justly called "whole blood" in contradistinction to citrated plasma, which contains only a small part of the vital blood constituents.

I suggested the citrate method of blood transfusion in 1915. Unger (then an intern at Mount Sinai Hospital) constructed at the same time his apparatus, which was the most popular among the different instruments used for blood transfusion. For a number of years both the Unger apparatus and the citrate method were used in this hospital. Both methods had their supporters among members of the staff. However, according to the darwinian law of "survival of the fittest," the citrate method is now the only method used at this hospital. More than three thousand transfusions are given every year at Mount Sinai Hospital, all by the citrate method. Transfusion apparatus have disappeared completely not only from this hospital, but from most institutions all over the world.

Scannell should know that reactions are not due to sodium citrate. They occur following any method of transfusion, unless instruments, solutions and tubing are kept immaculately clean. Ever since Rosenthal in 1933 pointed out the importance of these technical details, post-transfusion chills have been kept at a very low level.

The citrate method is the only practical method of blood transfusion. For this reason it is used in peace and war to the exclusion of other methods. Furthermore, blood banks cannot be used unless the citrate method is employed.

All other methods are of only historical interest, completely forgotten except by a few members of the profession whose names are connected with one or another apparatus.

Scannell states that whole blood and citrated blood are as different as black and white. Unless I am color blind, all apparatus which necessitate a direct connection between donor and recipient are definitely on the "black" list. The citrate method has supplanted them all and after thirty years continues to shine in bright "white" colors.

RICHARD LEWISOHN, M.D., New York.

MULTIPLE CARCINOMAS

To the Editor:—In the clinical note by Dr. C. A. Holland of Philadelphia in THE JOURNAL, June 2, appears the following paragraph:

> Irradiation was administered by Dr. Edward Chamberlain between June 10 and July 18, five days a week in daily dosages of 100 roentgens (one fourth in each of four positions: anteroposterior, posteroanterior, left posterior oblique and right posterior oblique) to a total of 3,000 roentgens. This heavy dosage was well tolerated, with a minimum of skin reaction. . . .

Unfortunately this paragraph does not truly set forth the essential factors that were used in the x-ray treatment of this remarkable case. In reading Dr. Holland's description of the therapy technic, one would naturally understand that each of the four skin portals received one fourth of 3,000 roentgens. Actually each of the four skin portals received 3,000 roentgens. On each of the thirty days on which treatments were administered the daily dose of 100 roentgens was administered to each of the four skin portals.

Dr. Holland's case report is a valuable one. I know you will agree with this because you would not have published it if you had not considered it valuable. Its importance would seem to warrant some statement to correct the misunderstanding. I have already received a letter from a radiologist in Florida asking for additional information in view of the likelihood that the factors as described in the case report were in error.

Had I had an opportunity to edit this paragraph about the irradiation of this patient's esophageal carcinoma, I would have changed the first sentence of the paragraph quoted to read as follows:

> Irradiation was administered under the supervision of Dr. W. Edward Chamberlain between June 10 and July 18 in daily (occasionally the interval was forty-eight or seventy-two hours instead of twenty-four hours) doses of 100 roentgens, to a total dose of 3,000 roentgens, to each of four skin portals, anterior, posterior and right and left oblique lateral.

W. EDWARD CHAMBERLAIN, M.D., Philadelphia.

"EPILEPSY, THE GHOST IS OUT OF THE CLOSET"

To the Editor:—A pharmaceutical house has distributed to physicians a pamphlet printed by the Public Affairs Committee called "Epilepsy, the Ghost Is Out of the Closet." An accompanying letter from the company's president quotes a favorable comment about the pamphlet by THE JOURNAL and states that I assisted in the preparation of the pamphlet. This is true, but paragraphs dealing with heredity contain statements which I know are untrue and were printed in this red covered edition over my protest. A corrected blue covered edition has been printed for distribution by the American Epilepsy League, 50 State Street, Boston.

WILLIAM G. LENNOX, M.D., Boston.

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, July 28, page 973.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Various centers, Jan. 18. *Oral.* Various centers, Oct. Final date for filing application is Oct. 20. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 24.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, May 27. Final date for filing application is Jan. 31. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written. Part I.* Various centers, Feb. 2. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 2-5 and Los Angeles, January. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Oct. 19. *Oral.* New York, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Written.* Chicago, Dec. 9. *Oral.* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1107 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Severance of Ileum During Performance of Appendectomy.—The plaintiff instituted an action for damages for malpractice against the physician defendant, Edwards, alleging, so far as is here material, that the physician negligently severed her ileum from the cecum in performing an appendectomy on her and negligently bound together small loops of her small intestine, resulting in an almost complete obstruction therein. The trial court overruled a motion for a directed verdict on the grounds of insufficiency of evidence to establish negligence on his part and the jury returned a verdict in favor of the patient. Later the physician made a motion for a new trial and from the denial of the motion appealed to the Supreme Court of Colorado.

Because the physician contended that the evidence adduced at the trial was insufficient to establish his negligence, the court undertook to summarize that evidence. The plaintiff, said the court, on being stricken with acute appendicitis, on the direction of the physician, was taken to a hospital in Denver where her appendix was removed by the physician. A few days later fecal matter began to exude from the incision and this condition continued. Several months thereafter another physician performed another operation, which disclosed, he stated, that the patient's ileum had been cut in two and that the two ends were about 8 inches apart. He effected finally a proper union of the loose ends of the ileum. The second physician could only account for the separation of the ileum by "an accidental severance with a knife or scissors." Another physician who assisted him in the second operation testified:

> The terminal ileum was found to be completely severed from the cecum. . . . It was severed or cut so the two ends were not approximating one another; they were several inches away. . . . The stump (of the lower portion of the separated ileum) looked like it might have been severed. I couldn't say definitely—with some sharp instrument of some sort.

The defendant testified that he did not either cut or sever the ileum in the course of the appendectomy and claimed that by placing a gauze packing around the ileum before the appendix was cut he precluded such a possibility. However, cross examination and the testimony of other medical witnesses tended to show that in the procedure actually followed in the questioned operation positive infallibility in the protection of the ileum from an accidental cut was not insured by the insertion of gauze packing. Both the physician defendant and another physician who assisted him in the operation testified that the patient's intestines were friable from inflammation caused by some preexisting infection and intimated that the fecal discharges through the incision came via a fistula from lesions resulting therefrom. In opposition, the physician and his assistant performing the second operation testified that the patient's intestines were normal and displayed no signs of any disease condition whatsoever. The physician defendant called five other physicians, who testified in response to hypothetical questions that had the ileum been severed completely the early death of the patient from peritonitis, caused by the consequent flooding of the abdominal cavity with fecal matter, would have been almost inevitable, and since the patient had not died, they believed that the intestine had not been severed during the course of the appendectomy. To controvert this testimony, on behalf of the patient there was presented expert medical testimony to the effect, apparently as revealed in the second operation, that through nature's protective processes the upper end of the severed bowel, following the line of least resistance, had become adherent to the abdominal wall at the place of the incision and there had formed a seal whereby the fecal matter from the organs above was discharged on the outside of the abdomen at that point, and that coincidentally the lower severed end of the intestine, being deprived of fluid, had sealed off and taken a position of repose. There was disagreement in the opinion of the medical witnesses as to the length of the period fecal discharges might continue after a severance of the ileum, the evidence of witnesses for the plaintiff being that such as factually were known to have occurred properly could be attributed to previous accumulations in the large bowel below the disjunction, while, contra, medical experts called by the defendant expressed the belief that the established rectal emissions demonstrated that there had been no severance of the bowel extract.

It is to be observed, continued the court, that the testimony of no medical witness so much as suggested that the ileum at the alleged area of disjunction was involved in the original condition of acute appendicitis or that it was necessary to cut it, treat it or do anything at all with it in order to remove the appendix. The defendant sought vindication from liability on a denial that he had in fact severed the intestine. While the testimony was in sharp conflict as to both factual and hypothetical matters, it seems certain to us that the evidence upholding the contention of the patient was amply sufficient to warrant the submission of the case to the jury and to support the finding of liability returned by it. The resolution of questions relating to the credibility and reliability of the various witnesses and the weight to be given their testimony are for the jury, and its conclusions in this field may not be disturbed by an appellate court.

In support of their arguments, the defendant cited a number of authorities relating to the safeguards from liability accorded by the courts to physicians in their practice, where the conduct in question was shown to be in pursuance of a recognized technic and where the unfavorable results were brought about by honest errors or mistakes in judgment in diagnosis or procedure. It seems to us, answered the court, that in so contending the defendant has lost sight of the circumstance that the transgression here charged was not directed to any dereliction in the performance of the appendectomy as such but to the needless and negligent injury to an unrelated organ, which all the medical witnesses agreed should not have been cut in any degree during the course of an appendectomy. In other words, severance of the ileum, at the point herein claimed, in the performance of an appendectomy would be, as was said in *Vergel v. Hartzell*, 8 Cir., 1 F. (2d) 633, cited by this court with approval in *Daly v. Lininger*, 87 Colo. 401, 288 P. 633, as:

> If a surgeon, undertaking to remove a tumor from a person's scalp lets his knife slip and cuts off his patient's ear, or if he undertakes to stitch a wound on the patient's neck and by an awkward move thrusts his needle into the patient's eye, or if a dentist, in his haste, leaves a decayed tooth in the jaw of his patient and removes one which is perfectly sound and serviceable, the charitable presumptions, which ordinarily protect the practitioner against legal blame where his treatment is unsuccessful, are not here available.

During the selection of the jury, counsel for the patient asked if any of the prospective jurors had "ever been an officer or employee of a company that insures against malpractice." This was the basis of a motion for a mistrial made by the physician which was overruled by the trial court. Ordinarily, said the Supreme Court, it is not reversible error in cases of this character to ask prospective jurors whether or not they are interested in a certain designated insurance company as officers, employees, stockholders or otherwise, since a plaintiff is entitled to inquire if any member of the panel has an interest in the corporation which has, or is supposed to have, indemnified the defendant against the liability asserted. However, the physician argued that the right so to inquire does not permit asking a blanket question concerning all insurance companies but must be limited to a certain company expressly named. Whatever may be the proper procedure hypothetically, answered the court in the present case because of the surrounding facts the trial court committed no error in the ruling made. Counsel for the patient, previous to propounding the question, could not ascertain from counsel for the physician what indemnity company was interested in the outcome of the case. The trial court then ruled that if the patient's counsel could not obtain the name of the insurance company involved from the physician's counsel "he is entitled to ask the general question." Following the ruling the physician's counsel divulged the name of the insurance company involved and presumably thereafter inquiries to the jurors concerning their interests or employment referred to the proper company by name. The court accordingly concluded that the question objected to was proper.

The judgment in favor of the patient was affirmed.—*Edwards v. Quackenbush, 149 P. (2d) 809 (Colo., 1944).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hereditary Anemia with Elliptocytosis.—The subjects of Cooley's report are 2 brothers, Jerome and Robert, coming from a family in which during five generations 19 of 29 boys born to women in the mother's line of descent exhibited a severe anemia. Sixteen of the 19 have died, 1 is said to have recovered and the other 2 are the present patients. No girls have been affected. The family history indicates that the disease is transmitted by unaffected females in the "sex linked" manner of hemophilia, or the "sex influenced" manner of pattern baldness. Both of the brothers exhibit in their blood a striking type of elliptocytosis, which is not found in any of the numerous siblings or in either parent. Robert, the elder, has never shown indications of serious illness but lives comfortably on average hemoglobin of 7.8 Gm., while Jerome, the younger, has always been more or less of an invalid, stunted, pale, and subject to frequent exacerbations of his anemia, in which transfusions become necessary. He has had more than twenty such periods during three years of observation. The blood of both boys has tended to be microcytic and hypochromic, and each has had periods of polycythemia with counts above 6,000,000. Jerome's frequent relapses have apparently been due to infection, and the fact that at these times his blood shows fragmentation makes it seem probable that there is a hemolytic element present. His episodes of respiratory infection are described by his parents as asthmatic. They are probably bronchitis. The patient's white cells immediately following a relapse have usually shown a neutrophil count above 20,000. A striking change in Jerome's cells followed a splenectomy. Robert's cells have never shown anything similar. It is believed that the operation influenced favorably the fundamental disease process and that, if by suitable prophylaxis the infectious element can be minimized, something approaching a cure can be hoped for. This anemia adds one more to the list of the "refractory" anemias, uninfluenced by any therapy, except occasionally by splenectomy. All of these refractory anemias are due to constitutional defects in the hemopoietic system. Sickle cell anemia, Mediterranean anemia and a familial anemia reported by Strauss and Daland are other examples of refractory anemias. This last is also characterized by elliptocytes.

Persistence of Pneumococci After Sulfonamide Treatment.—Goodwin and his associates studied the persistence of pneumococci in sulfonamide treated cases of pneumonia by examination of sputum and throat cultures from 43 patients at the Boston City Hospital before and at intervals during and after treatment with sulfathiazole or sulfadiazine. Three of the patients were studied during two attacks of pneumonia. Considerable variations were found in the persistence of pneumococci. Of the strains of pneumococci found before the sulfonamide therapy was started, about 30 per cent persisted throughout the period of observation or were obtained intermittently during this time. Three fourths of the remaining strains could no longer be found after the third day of treatment. New types of pneumococci which were not found in the pretreatment cultures appeared in the specimens studied during or after sulfonamide therapy in a considerable proportion of the cases. Most of the strains which first appeared during sulfonamide therapy could no longer be found after that treatment was completed. Multiple types of pneumococci were found more frequently in patients with a history of chronic respiratory infections. In these cases and in those with purulent complications of the pneumonia there was a greater tendency for the pneumococci to persist than in uncomplicated cases. The persistence of pneumococci was not related to the failure of the patient to develop antibodies for the homologous types.

Sensitivity to Sulfonamides.—The untoward reactions resulting from the administration of sulfonamides may be divided into (1) direct toxic effects such as vomiting and cyanosis, (2) mechanical effects due to precipitation of the drug or its acetyl derivative in the urinary passages and (3) allergic reactions such as drug fever and eruption. Kent and Diefendorf studied the time of appearance of certain of the allergic reactions to the drugs and the incidence and time of onset of allergic reactions when the drug was readministered after being withheld for an interval. Of 472 patients who received one course of sulfathiazole, 110 exhibited some form of reaction to the drug, and approximately one half of these had allergic reactions. Regarding the percentage of patients developing drug fever on any one day the therapy is given, the authors say that the curve rises to a peak of 9.9 per cent on the ninth day and thereafter drops sharply. Thus, if a patient has had no reaction after nine days of therapy his chances of developing one subsequently on the same administration diminish rapidly. Of 103 patients receiving sulfathiazole twice, 22 patients exhibited sensitivity reactions. Of the patients showing manifestations of sensitivity on the second course, drug fever occurred within the first two days of readministration in all of the patients who had fever on the first course. Three fourths of them had had no reaction on the first course. Of the patients who reacted to the second administration but not the first, none developed a reaction before nine days had elapsed from the time the first course was started. The appearance of sensitivity reactions on the second course is not related to the total time the drug is administered or to the absolute duration of the interval between courses. Sensitivity reactions may follow an initial course, which may be as short as two or three days. No influence of dosage on the incidence of sensitivity reactions was demonstrated. The short time between the beginning of readministration and the appearance of drug fever is regarded as evidence that an allergic state was present at the time the second course was started. An interval between courses serves to demonstrate that an initial administration has sensitized an individual to subsequent courses of the drug.

Ultraviolet Light Control of Air Borne Infections.—Wheeler and his associates investigated the efficiency and practicality of ultraviolet irradiation as a method of reducing the spread of respiratory infection in navy barracks. Ultraviolet lights were installed at similar locations in all the lighted barracks. Overhead fixtures provided indirect irradiation directed to the upper air of the barracks. Lights were also installed under the bunks with irradiation directed downward to the floors and lower air, where bacteria laden dust particles are found to be the most numerous. There was a 25 per cent reduction of respiratory illness in the barracks equipped with high intensity sources (235 watts of ultraviolet energy per dormitory sleeping quarters of 112 men) as compared with illness in the adjacent control barracks. This effect was most noticeable in the early winter months, when illness rates were at a high level throughout the camp. At this time the reduction of incidence in barracks with irradiation as compared to the controls was approximately 35 per cent. Streptococcic illness and carrier rates were at a low level. These low levels were not further reduced among men living in irradiated barracks. Bacterial counts from air samples in irradiated barracks showed a 50 per cent reduction in total saprophyte colony counts as compared with nonirradiated control barracks. Beta hemolytic streptococci isolated from air and dust were found more frequently and in greater numbers in control barracks than from irradiated sleeping quarters. In view of the fact that reduction in morbidity rates was pronounced in the high intensity irradiated group only in the first months of the study period, the results of the experiment of 1943-1944 should be interpreted with caution.

*Evaluation of Roentgen Therapy in Filariasis. H. L. Jaffe.—p. 483.
Direct and Indirect Radiotherapy. B. Grynkraut.—p. 491.

Roentgen Therapy in Filariasis.—Jaffe evaluates the results of roentgen therapy in filariasis by comparing the course of the disease in a group of 50 patients treated by roentgen rays with that of an untreated group of the same number. Three months after treatment the course of filariasis was similar in the irradiated and in the untreated patients. Several patients derived benefit from roentgen therapy in that some glandular swellings were reduced in size and were rendered less painful. No harmful effects were observed as a result of this roentgen treatment. Total body irradiation offers no advantage over local roentgen therapy and at times does not appear to be as effective in relieving the pain of enlarged glands or in reducing their size. Roentgen therapy did not influence the frequency, duration or severity of recurrent attacks after periods of remission. Several patients who complained of a pleuritic type of pain presented lesions of a transitory and migrating type of chronic pneumonitis affecting one or both lungs. These patients were afebrile and showed a normal white blood cell count.

*Avertin Poisoning with Acute Yellow Atrophy of Liver and Toxic Nephrosis. Dorothy H. Andersen.—p. 284.

Spinal Anesthesia in Hyperthyroidism.—Spinal anesthesia has been considered part of the operative management only in those cases which have not been brought under sufficiently satisfactory control by the usual measures. Spinal anesthesia is not administered with the purpose of providing or even assisting the anesthesia for the surgical procedure. The purpose is solely to anesthetize that part of the sympathetic nervous system which innervates the adrenal glands and to reduce the secretion of epinephrine immediately before the operation. It is the custom at the author's clinic to anesthetize the apprehensive and toxic patients with intravenous sodium pentothal in their rooms without the patient knowing that the day of operation has arrived. While asleep under sodium pentothal, the patient is taken to the operating room. The anesthesia is then usually continued with some inhalation agent. For the few patients who have been especially resistant to the preoperative treatment, spinal anesthesia is added. The spinal anesthetic is administered when the patient arrives in the operating room and after the inhalation anesthesia is begun. The typical picture is that the blood pressure and pulse run a more even and less elevated course than can be expected in even less toxic patients without spinal anesthesia. The awakening is more quiet, the patients are more content and less active. Spinal anesthesia to the level of the fifth or fourth thoracic segment seems to have a beneficial effect on patients in thyroid crisis and thyrotoxic patients undergoing operation.

Tribromoethanol Poisoning with Atrophy of Liver and Toxic Nephrosis.—Andersen reports the case of a child, aged 8, in whom tribromoethanol anesthesia was followed by acute yellow atrophy of the liver, uremia and death in fourteen days. Since the dose was conservative and the administration was according to standard procedure, the author thinks that the patient was unusually susceptible to the drug. The author presents data on 16 cases collected from the literature in which death followed tribromoethanol anesthesia and postmortem examination showed hepatic or renal damage or both. The pathologic changes are comparable to those found in delayed chloroform or carbon tetrachloride poisoning.

Enzyme Inhibitory Action of Alkyl Aryl Sulfonate.—The information available concerning the toxicity of orally ingested wetting agents indicate a relatively low toxicity for alkyl and aryl sulfates and sulfonates. Such toxic manifestations as have been reported are largely explainable on the basis of gastrointestinal irritation. There is also in vitro and in vivo evidence indicating that these substances will denature proteins and inhibit peptic and tryptic activity. Freeman and his collaborators decided to determine the oral toxicity of a detergent substance which they designate as NAS and which is essentially a purified mixture of alkyl aryl sodium sulfonates. In vitro experiments indicate that this wetting agent will inhibit enzyme activity, but the feeding experiments with rats, dogs and human beings indicate that in vivo this inactivation was not of sufficient magnitude to alter digestion and absorption of foodstuffs materially. When the substance was administered daily to rats for sixty-five days in an amount constituting 0.5 per cent of the diet, it did not significantly influence growth or reproduction. One Gm. daily for six months did not affect the maintenance of adult dogs. The normal cellular composition and hemoglobin content of the blood in both dogs and rats as well as the normal gross and microscopic appearance of the stomach, liver, kidney and bone marrow are all indications that there was no significant systemic toxic effect from the substance. In dogs, normal dye clearance by the liver and the serum phosphatase values furnish further evidence that the function of the liver was not impaired. In relatively large daily amounts the substance produced irritation of the gastrointestinal tract of dogs as evidenced by the passage of loose stools and mucus. Death probably resulted from inanition and dehydration when sufficiently large doses (3 or 4 Gm. daily) were fed. In human subjects daily ingestion of 100 mg. for four months produced no change in the cellular composition and hemoglobin of the blood nor any demonstrable effect on the kidney function. The substance apparently also had no effect on absorption from the gastrointestinal tract, as indicated by body weight and analysis of the fecal fat and nitrogen.

Propeptans in Treatment of Ragweed Hay Fever. S. W. Landau and L. N. Gay.—p. 159.

Vitamin C in Hay Fever.—Friedlaender and Feinberg investigated the vitamin C content of the blood in hay fever patients who were given vitamin C and in some who received no vitamin C. They found that patients with hay fever have a normal blood level of vitamin C. Large doses (500 mg. daily) of vitamin C produce the usual saturation blood levels but do not change the course of the hay fever or asthma. The inability to detect any deficiency of the vitamin C nutrition in seasonal hay fever and asthma patients is in keeping with the absence of therapeutic results when large amounts of vitamin C are administered in these conditions.

Inhalant Sensitization in Guinea Pigs.—The Courtrights attempted to analyze several components of weather and their actions on inhalant sensitization and shock in guinea pigs. They report reactions of 350 guinea pigs sensitized and shocked by inhalation of horse dander in various controlled weather conditions. More than 1,500 shock exposures were made. The conditions under which the greatest number and most severe anaphylactic reactions occurred were (*a*) shifting from hot dry air to low barometric pressure, (*b*) shifting from low pressure to hot dry air and (*c*) shifting from hot moist to cold dry air without the allergen and back to hot moist with the allergen. The single weather conditions, in the order of the number of severe reactions which occurred in each, were (*a*) hot dry, (*b*) room air, (*c*) cold dry, (*d*) hot moist and (*e*) cold moist air. The single weather conditions, in the order in which the greatest number of all types of reactions occurred, were (*a*) hot moist, (*b*) cold dry, (*c*) hot dry, (*d*) room air and (*e*) cold moist air. The single weather conditions, in the order in which the most severe reactions in the first shock exposure occurred, were (*a*)

hot dry, (*b*) hot moist, (*c*) cold dry, (*d*) room air and (*e*) cold moist air. In one well controlled experiment the experimental low pressure condition was conducive to a significantly higher number of reactions than was that of high pressure.

Mixed Tumors of Salivary Glands.—Kent and his associates operated on 14 mixed tumors of the salivary glands over a period of seventeen years. The youngest of the patients was 27, the oldest 64 years of age. The average duration of symptoms was 7.6 years. The mean age of onset was computed as 36 years. The sex incidence was much higher in the female than in the male patients, the ratio being 11:3. All but 2 of the mixed tumors occurred in the parotid gland; the 2 remaining ones were in the submaxillary gland. All of the lesions except 1 were well encapsulated. In 5 cases the capsule was ruptured, in the others it remained intact. The only constant symptom was the presence of a lump, mass or swelling. Salivary tumors usually turn out to be much more extensive than originally contemplated. In this series the tumors were removed by the block method in 10 cases. In the 2 submaxillary tumors the entire gland was removed and the digastric triangle widely dissected. The tumor was enucleated in 2 cases. Six of the patients had a resultant facial paralysis, which was permanent though not extensive in 3 instances. A temporary salivary fistula ensued in 2 of the cases. The results have been good. There was 1 recurrence which responded to irradiation. The follow-up has varied from six months to sixteen years, the average follow-up period being slightly less than nine years.

Heredity of Rh Blood Types.—Wiener and Sonn present data on the Rh types in a series of 91 families with 161 children. A single apparent exception to the theory of six allelic genes has been shown to be due to illegitimacy. These data combined with previously published results make a total of 197 families with 463 children tested by the authors for the Rh blood types. The satisfactory agreement between the observations and expectations under the theory justify the medicolegal application of the Rh tests for the exclusion of paternity. To date, in 102 cases of disputed paternity, tests for the Rh types have been carried out together with the usual A-B-O, A_1-A_2 and M-N tests. In 4 cases the accused man was excluded by the Rh tests; in 2 of these cases he was also excluded by one of the other tests, but in 2 cases the woman's false accusation might have been believed had the Rh tests not been performed.

Fatal Cardiac Tamponade Following Sternal Puncture.—Scherer and Howe report the history of a man aged 31 in whom several unsuccessful attempts were made to aspirate marrow from the sternum. The depth to which the needle was inserted at times reached about ¾ inch. Repeated attempts at several levels resulted only in the aspiration of a small amount of blood tinged fluid. The procedure was given up as unsuccessful. Shortly thereafter the patient became pale, semicomatose, breathing noisily and with pupils dilated. The pulse was thready and rapid and the blood pressure not determinable. The foot of the bed was elevated, nikethamide and epinephrine were given and artificial respiration was started. The patient died suddenly after a few minutes, approximately thirty minutes after the unsuccessful aspiration. Necropsy revealed a through and through needle puncture wound of the sternum just below the sternal angle, with slight periosteal extravasation of blood about the point of exit on the posterior surface of the sternum. Directly beneath this wound there was a similar needle puncture wound through the parietal pericardium. The pericardial sac was distended by approximately 350 cc. of fresh blood, and the heart was completely surrounded by fresh clot. Just beneath the puncture wound of the parietal pericardium there was a triangular laceration of the musculature of the right ventricle 1 cm. in greatest diameter. The authors say that this is the second death from sternal puncture recorded in the literature and the first reported necropsy on such a case.

Reading Disability a Pediatric Problem.—Wolf shows that disability in reading may play a part in the physical complaints and emotional tensions found in school children, particularly in those 9 to 10 years of age or older. From the fourth, fifth and sixth grades on, the ability to read assumes an increasingly important part in nearly every school subject. A youngster unable to compete with his classmates because he cannot read finds himself at a disadvantage, and repeated failure results in unhappiness for which he may try to compensate in various ways. He may develop into a behavior problem, becoming sullen and negativistic toward his teacher and classmates. He may become the bully or withdraw from contacts with the group. On the other hand, he may develop bizarre physical complaints varying from mild headaches to severe digestive disturbances, fainting spells or convulsive seizures. He may manifest both emotional and physical symptoms. A case recently encountered in the pediatric outpatient department of the University of Minnesota Hospitals illustrates the point. A frequent error of parents and teachers is to think of the child as dull and stupid. Measured intelligence and rapid school progress

after remedial treatment have proved otherwise Uncorrected conditions of the eye or ear may be responsible for the reading difficulties The physician should look for muscular imbalance, which may cause a lack of fusion of visual images Some children need additional corrective eye muscle training Islands of deafness may be unrecognized Other factors that play a part in reading disability are inadequate instruction, emotional problems and cerebral factors The theories of causation due to lefthandedness, to mixed eye-hand dominance in the cerebral hemispheres, have been open to serious question and criticism Most if not all of the difficulties can be relieved by proper guidance

Growth of Children Receiving Evaporated Milk—Rhoads and her associates used various criteria of growth and nutrition in following the progress of a group of white and Negro children who received evaporated milk as the sole milk supply from birth through 5 years of age The children were from low income families and were observed at periodic visits to the clinic of the Children's Hospital of Philadelphia Except for the milk and vitamin supplements which were provided by the clinic, the remainder of the food was the customary home diet Group 1, as controls, received irradiated evaporated milk as the sole antirachitic Group 2 received nonirradiated evaporated milk plus 1 tablespoon of cod liver oil daily Group 3 received irradiated evaporated milk plus 10 drops of carotene daily, equivalent approximately to 2 250 U S P units of vitamin A Group 4 received irradiated evaporated milk plus 10 drops of carotene and ½ tablespoon of brewers' yeast The brewers' yeast furnished approximately 0 5 mg of vitamin B and 0 2 mg of riboflavin After the child reached the age of 1 year the evaporated milk was usually consumed as a beverage at the rate of one 14½ ounce can daily per child The nutritional adequacy of evaporated milk for growth and development through infancy and early childhood was demonstrated Dietary supplements of vitamin A or vitamin B complex were found to be without demonstrable effect by the criteria used

Single Intravenous Dose of Sodium Sulfadiazine in Meningococcic Meningitis—The 9 cases of meningococcic meningitis reviewed by Winter were observed at the Department of Pediatrics of the United States Naval Hospital, San Diego, Calif The treatment varied from the customary in that a single large intravenous dose of sulfadiazine was given Eight patients received 2½ grams per pound of body weight, 1 patient received 2 grams per pound This single dose of sodium sulfadiazine resulted in complete recovery This dose will maintain a sulfonamide level in the spinal fluid and blood long enough for rapid recovery With the present method of treatment there is every indication that the present quarantine period of meningococcic meningitis is unnecessarily long It is possible that less than 2 grams per pound of body weight will be adequate to give the same result Further studies will be necessary to determine the minimum single dose of sulfadiazine sufficient for rapid recovery High sulfadiazine levels are shown to be well tolerated if adequate alkalization of the urine is maintained Spinal fluid cultures were sterile twenty-four hours after a single large intravenous dose of sodium sulfadiazine, thereby lessening the chance for complications and sequelae

Ten years' Experience with BCG—Rosenthal and his associates say that ten years ago the Trice Laboratory and Clinic of the Chicago Municipal Tuberculosis Sanitarium set about to determine whether the bacillus of Calmette and Guerin (BCG) was safe for animals and man and whether this form of vaccination against tuberculosis was beneficial It was found that BCG was entirely innocuous both locally and generally in animals studied over a period of ten years and in infants studied over a period of seven years In 1,204 vaccinated children in whom no contact with tuberculosis was known there were 3 cases of tuberculosis and 1 death from the disease, whereas in 1,213 controls there were 23 cases of tuberculosis and 4 deaths from the disease In 98 vaccinated newborn infants who were in contact with tuberculosis following vaccination there was 1 case of tuberculosis and no deaths, whereas in 63 controls there were 4 cases of tuberculosis and 3 deaths Considering the contact and noncontact group as a whole, there were 27 cases of tuberculosis in the control group against 4 cases in the vaccinated, there were 7 deaths from tuberculosis in the control group and 1 in the vaccinated The authors conclude that in the first seven years of life BCG vaccination is of definite value in the prevention of tuberculosis

Pancreatoduodenal Resection.—Cattell reports observations on 18 patients on whom pancreatoduodenal resections were performed There were three deaths The one stage operation was employed in 5 cases and the two stage operation in 13 Since many patients are over 60 years of age, have severe obstructive jaundice and are in poor condition, the two stage operation is considered necessary in most cases An antecolic long loop cholecystojejunostomy is recommended since it permits rehabilitation and does not complicate the resection Restoration of the external pancreatic juice to the intestine is accomplished by direct anastomosis of the duct of Wirsung to the jejunum as a means of avoiding the serious complication accompanying pancreatic fistula and in order that normal pancreatic and digestive function may be accomplished Antecolic gastric, biliary and pancreatic anastomoses are advised Results for a period up to two years are reported, with satisfactory results in 13 of 18 cases

Paroxysmal Tachycardia· Vascular Collapse—Wolff analyzes 253 cases of paroxysmal tachycardia with reference to the occurrence of vascular collapse, which occurred in 16 per cent Extreme tachycardia induces vascular collapse in more than half with rates at or above the critical level, which is in the vicinity of 200, below this level collapse is not induced by tachycardia alone The critical level is not lower in cases of myocardial infarction or other types of heart disease, with the exception of aortic valvular disease, than in normal heart Extremely rapid ventricular rates induce vascular collapse in about half the cases with normal hearts and with coronar heart disease, in about three fourths of the cases of acute or

recent myocardial infarction and in all the cases of mitral stenosis Causes other than tachycardia must be suspected when collapse is associated with rates well under 200 or when termination of the abnormal rhythm or significant reduction of heart rate is not promptly followed by resumption of a normal circulation

Osteitis Deformans —At the Mayo Clinic prior to January 1938 a diagnosis of osteitis deformans or Paget's disease was made in 367 cases Dickson and his associates analyze the records of these cases They attempt to correlate the clinical manifestations of the disease with the roentgenologic evidence As the term osteitis deformans implies, Paget believed the disease to be a chronic inflammatory process Local heat may be demonstrated in the bones particularly in those which are easily palpable The highest incidence of the disease occurred during the sixth decade, a third of the 367 patients falling in this group Sixteen of the patients had relatives with the same disease Seventy-five patients had no complaints prior to the time of diagnosis and had not been aware of anything unusual as far as the bone disease was concerned The disease was discovered incidentally in the course of a roentgenographic investigation On the basis of roentgenologic variations 200 cases have been classified into 100 with the sclerotic phase and 100 with the combined phase In the pelvis the sclerotic phase is characterized roentgenographically by a homogeneous increase of the density of bone, with details of the cancellous trabeculae no longer perceptible The combined phase has a more complex roentgenographic picture, it represents nonhomogeneous alterations of density of bone Areas of osteoporosis osteosclerosis and cysts are demonstrable The most striking alteration observed in the blood of patients with osteitis deformans is an elevation of the serum phosphatase Higher levels for serum phosphatase were observed in the combined than in the sclerotic phase Pathologic fracture is one of the most common complications Seventy-seven pathologic fractures were encountered in 62 of the patients included in this series They were most frequent during the combined phase The fracture usually heals with abundant callus formation In 3 cases sarcoma and in 1 case a benign giant cell tumor complicated the osteitis Localized or diffuse areas of finely mottled osteoporosis of the skull are thought to be an early roentgenographic manifestation of osteitis deformans In a study of 117 cases in which there was involvement of the skull, 26 instances of osteoporosis circumscripta were encountered Subsequent roentenologic examination in some instances demonstrated multiple shadows of increased density typical of osteitis deformans, which appeared in the areas of osteoporosis It would seem that osteoporosis circumscripta is an early roentgenographic manifestation or precursor of osteitis deformans of the skull. Earlier observers held the view that the skull and tibia were the most frequent sites of the disease The authors found that the most frequent site is the pelvis This high incidence of involvement of the pelvis, 243 of 307 cases, may be partially accounted for by the frequency with which the diagnosis was made during urologic examination

Medical Treatment of Refractory Peptic Ulcer —According to Winkelstein and his associates only a small percentage of patients with peptic ulcer are cured medically, many go through life with mild symptoms and about 25 per cent are refractory and require intensive medical or surgical therapy For this purpose the usual Sippy therapy seems inadequate because it has a number of disadvantages, one of the more important being that it does not effect interdigestive neutralization, especially of the night secretion Methods to control the harmful nocturnal hypersecretion included gastric aspiration, atropine, sedatives, olive oil and alkalis given separately or in combination As a result of the failure of these measures there arose the idea of continuous intragastric drip therapy throughout the twenty-four hours These colloids, besides preventing alkalosis, are antiseptic and astringent and can be substituted

for the milk sodium bicarbonate mixture wherever the latter is contraindicated, as in cases of an allergic reaction or an idiosyncrasy toward milk The nutritive value of milk and the simplicity of the apparatus required for its administration favor its use whenever conditions permit A mixture of milk and alumina gel has also been tried and found adequate Experience of thirteen years with the continuous intragastric drip method has demonstrated its clinical efficacy The technic is learned quickly, so that nearly all the patients can administer it to themselves at home during the night Using a vessel similar to the ordinary enema can as a milk container and a rectal drip indicator, they can operate the drip at home during the night and carry on their work during the day, thus continuing a 'home cure" for as long a time as may be necessary Most of these patients are "tube broken' having had various gastric analyses performed on them, so that they do not find the method difficult The authors have used the intragastric drip procedure on 60 ulcer patients who were refractory to the usual medical therapy Twenty two of these are cited as examples of the successful application of this form of therapy

Removal of Vagus Innervation of Stomach in Gastroduodenal Ulcer—Acting on the conception that the hypersecretion of gastric juice in gastroduodenal ulcer is largely neurogenic in origin Dragstedt and Schafer have treated a series of patients with this disease by an operation designed to remove permanently and as completely as possible the vagus innervation of the stomach Supradiaphragmatic division of the vagus nerves has been performed on 13 patients with duodenal ulcer, on 1 patient with gastric ulcer and on 1 with a gastrojejunal ulcer The patient with gastric ulcer has been apparently cured of his disease, as judged by the disappearance of symptoms and by x-ray and gastroscopic evidence All but 1 of the patients with duodenal ulcer have been greatly improved or have been cured, although 3 patients have required gastroenterostomy because of persistence of obstructive symptoms The patient with the gastrojejunal ulcer, although improved, has been continued on medical management The excessive continuous night secretion of gastric juice has been greatly reduced by the vagus section thus providing additional and perhaps conclusive evidence that this abnormality is neurogenic in origin The striking improvement in these patients is in harmony with the view that gastroduodenal ulcer is a psychosomatic disease and that the central nervous system affects the stomach via the vagi, probably chiefly through greatly augmenting the secretion of gastric juice

Effects of Clostridium Welchi Toxin on Body Tissues—Frazer and his associates studied the effect of Clostridium welchi toxin on tissues and fluid substrates in vitro, in animals and in human subjects The experiments indicate some points which may be significant in determining the local spread of infection and they also open up two new lines of investigation with regard to the systemic reactions—namely, demyelination and fat embolism Cl welchi toxin will cause rapid destruction of red blood cells, and there is evidence that hemolysis occurs The other changes in the blood consist of flocculation of chylomicrons and the breaking of lipoprotein complexes The fact that flocculation of chylomicrons is caused by the serum of these patients may be significant in relation to the production of fat emboli The occurrence of demyelination is an effect of lecithinase or may be secondary to fat embolism in the central nervous system With regard to the origin of the fat in clostridial fat embolism there are two possibilities The first is the free fat which is liberated from adipose tissue and muscles and can be seen as large globules in in vitro studies and in the material from the site of tissue destruction The second is from flocculated chylomicrons and the fatty material set free from broken lipoprotein complexes In experimental studies there seems little doubt that the fat must be derived from the site of local destruction

Clinical Importance of Renal Function Tests in Pregnancy R Nick Rome—p 289
*Renal Function Tests in Pregnancy V I Krieger—p 290
Treatment of Postirradiational Ulcers by Radon Ointment A G S Cooper and D F Robertson—p 297

Renal Function Tests in Pregnancy—Krieger discusses results of an investigation carried out by an obstetric research committee since 1926 on biochemical tests in relation to their value in the toxemias of pregnancy Kidney function was estimated by tests on the blood and the urine The blood was examined for its content of urea, nonproteim nitrogen, uric acid creatinine and undetermined nitrogen A twenty-four hour specimen of urine was examined for its content of urea, ammonia and total nitrogen, and its diastatic index was calculated Maclean's urea concentration test was performed Liver function was investigated by testing pigmentary function and carbohydrate metabolism The pigmentary function was assessed by examination of the blood by Fouchet and van den Bergh tests and by testing the urine for bile pigments and salts and also for urobilin Carbohydrate metabolism was estimated by the levulose test The urine was tested qualitatively and quantitatively for the presence of diacetic acid and acetone as a means of detecting the presence of acidosis The blood urea content and Maclean's urea concentration test were found to be the most useful means for determining renal function while the Fouchet and van den Bergh tests were found to be the most useful in the estimation of liver function Many thousands of renal function tests have been performed Tests cannot replace thorough clinical investigation but their results are weighty

evidence which cannot be disregarded. The management of a patient on clinical data alone is often sufficient in one pregnancy, but there will be no evidence of its effects on the kidneys. Thus, information of value in later pregnancies is not available. One pregnancy may result in a living baby and a surviving mother. The mother, however, may not be able to withstand the effects of toxemia in later pregnancies. Renal function tests are practically the only means by which some idea of this possibility can be obtained. In cases in which the clinical condition is satisfactory and renal function is poor, and when the results of renal function tests do not improve after a few days of treatment, termination of pregnancy is advisable, since follow-up examination indicates that, even if the present pregnancy terminates satisfactorily, later history may be unsatisfactory.

*Pathogenesis of Eye Complications of Arsphenamine Dermatitis. S. von Pastinszky.—p. 480.

Eye Complications of Arsphenamine Dermatitis.—Of 3 patients who had dermatitis with eye complications as the result of antisyphilitic treatment with arsphenamine, the first had a panophthalmitis, the second a superficial keratitis punctata and the third corneal edema. Von Pastinszky has observed that conjunctivitis is frequent in arsphenamine dermatitis with ocular involvement, but superficial keratitis is rare and corneal ulcers with perforation and panophthalmitis are still rarer. This is due to the fact that the cornea is not as likely to develop allergic inflammations as is the conjunctiva. Secondary infection, lack of resistance, hypovitaminosis and perhaps mechanical factors may play a part in addition to the allergic factor. The allergic nature of the inflammation is indicated by the extreme eosinophilia demonstrable in the conjunctival secretion.

Pain in Region of Root of Fourth Lumbar Segment. G. von Reis. —p. 344.

Cancer of Neck of Uterus in Pregnancy.—Of 1,168 cases of cancer of the neck of the uterus treated from 1931 to 1942, 22 (1.9 per cent) were complicated by pregnancy; 11 patients were over 35 and 4 were under 30. The growth of the tumor was not affected by pregnancy, but parturition seemed to have an unfavorable effect. Jessen considers cesarean section and supracervical amputation of the uterus justifiable when the tumor is found shortly before the end of term. When abortion has been induced because of cancer of the cervix, radiotherapy should be instituted as soon as possible.

Correlation Between Heart and Arm.—Ask-Upmark has observed a characteristic arm syndrome in connection with certain diseases of the heart, particularly coronary insufficiency, which consists of humeroscapular periarthritis, infiltrations of the palmar aponeurosis and edema of the fingers. The symptoms, unilateral as a rule, may occur together, but the shoulder changes and the palmar infiltration are most often present. The syndrome is one of the most common complications after a heart infarct. In predisposed persons, especially women, a cardiac syndrome consisting of palpitations, premature beats and oppression may be registered in connection with arm movements.

Determination of Gas Exchange in Lungs with Relation to Metabolism Together with Hormonal and Vegetative Functions. L. Herlin.—p. 531.

Myotonia Atrophica and Mental Changes.—Since 1941 Thomasen has observed 94 patients in nineteen families with myotonia atrophica and with cataract in some members. Deceased members of the families are also believed to have had the condition. Cataract, senile or presenile, may be the first manifestation of the disease. Reduced intelligence is the most conspicuous psychic change in the disorder. Of the 94 patients only 20 have fairly normal intelligence. Most patients lack initiative and are indolent and carefree. The muscular symptoms include myotonia, muscular atrophy and early muscle fatigue. Fertility is diminished. Atrophy of the sternocleidomastoid muscle is of differential diagnostic significance. Psychiatrists, especially in institutions for the feebleminded, should keep dystrophia myotonica in mind; it is transmitted by dominant inheritance, and examination of the patient's relatives will usually reveal overlooked or misinterpreted cases.

Ten Years' Work for Standardization of Hospital Equipment. F. Bauer. p. 585.

Regulation of Respiration During Muscular Work.—Nielsen and Asmussen state that during muscular effort respiration is probably regulated by reflex impulses from the working muscles to the respiratory center which increase the excitability of the center to carbon dioxide in proportion to the intensity of the work. Sensory nerves are believed to lead the impulses to the respiratory center. Hyperventilation in heavy work may be due to substances produced in the working muscles when the oxygen supply fails. In patients with poorly capillarized muscles or weakened peripheral circulation hyperventilation may occur on slight physical exertion because of a beginning deficiency in the oxygen supply.

Oculogyric Instability as Initial Symptom in Multiple Sclerosis.—Jensen reports that oculogyric instability was established in 70 per cent of 50 patients (23 men, 27 women) with multiple sclerosis. It was demonstrable in 12 of the 14 patients with duration of the disorder of a year or less. For examination of the circumductive leading movement the patient is requested to keep his head still and follow attentively with the eyes an object, such as the end of a fountain pen, shown to him and then made to describe steadily a not too large circle about 50 cm. in front of his face. In patients with multiple sclerosis, even in the initial stage, the circular movement on both sides often proceeds in a series of jerks, and an irregular snappy nystagmus occurs every time the eyes reach one or two definite points in the path of the object. The second phenomenon is bilateral and occurs most often in the upper quadrants of the range of vision, but not in the horizontal line or the vertical meridian.

Book Notices

Peripheral Nerve Injuries: Principles of Diagnosis. By Webb Haymaker, Capt., M. C., A. U. S., Neuropathologist, The Army Institute of Pathology, Washington, D. C., and Barnes Woodhall, Maj., M. C., A. U. S., Chief, Neurosurgical Section, Walter Reed General Hospital, Washington, D. C. Cloth. Price, $4.50. Pp. 227, with 225 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

This is a carefully organized manual which painstakingly details the fundamentals of anatomy, physiology and the diagnosis of injuries of the peripheral nervous system. It is short, interestingly presented and to the point. It is divided into three major sections. In the first section the segmental and peripheral nerve supply of skin, muscles and skeleton are analyzed. The authors have crystallized out all that is known with certainty and have eschewed the more theoretical and controversial aspects of innervation. Excellent charts and illustrations adapted from Foerster and Bing are included in this section. The second section describes the examination of the peripheral nervous system. Here are succinctly described all the maneuvers and tricks in the armamentarium of the neurosurgeon. The authors discuss in this section all the influences which modify the clinical picture of peripheral nerve injuries such as pain or associated vascular injuries. This is an important factor in diagnosis and is not generally known. In this section are numerous line drawings and photographs, graphically illustrating the various technics in the examination of peripheral nerve function. The third and last section details the findings in injuries of the plexuses and peripheral nerves. Excellent anatomic drawings of the involved plexuses and nerves and numerous photographs of actual cases are presented. With a bare minimum of words the authors describe all that can be found when a nerve or plexus is injured. This useful manual is an ideal reference book for any one whose practice includes injuries of the peripheral nerves. Its clarity and brevity make it a valuable item for medical students and general practitioners. It is a necessary reference textbook for any army surgeon or neurosurgical assistant. The only fault that the book seems to have is that it was not published four years ago.

Fisiologia endocrina. Por Amado Ruiz Sánchez. Tesis de doctorado, Universidad de Guadalajara, Hospital civil. Tomo II. Paper. Pp. 416, with 166 illustrations. Guadalajara, 1944.

This book is the continuation of one which was previously published by the author with the name of "Apuntes de Fisiologia Endocrina." It deals with the anatomy, embryology, histology and physiology of the genital organs, thyroids, adrenals, pancreas, parathyroids, pineal body and thymus, as well as with endocrine abnormalities and with diseases due either to endocrine hypofunction or to endocrine hyperfunction. The pictures showing endocrine abnormalities and those of patients with endocrine diseases belong to the files of the Endocrinologic Department of the Civil Hospital of Guadalajara. The last two chapters deal with the correlation between endocrine hormones and vitamins and between malnutrition and endocrine diseases and also with the chemistry of genital hormones. The final section includes 442 references. The book condenses the interesting panorama of the fascinating subject of endocrinology.

The Common Cold and How to Fight It. By Noah D. Fabricant, M.D. Cloth. Price, $1.50. Pp. 107, with 9 illustrations. Chicago and New York: Ziff-Davis Publishing Company, 1945.

This is a comprehensive statement of what we know and an acknowledgment of what we do not know about the common cold. It is written for the lay reader and is of interest to the doctor because he is so frequently called on to recommend books to his patients. This book is interesting, readable and reliable. It should be helpful and encouraging to readers, without arousing false hopes which must only be disappointed later.

Sobre el caracter epiléptico: La histeria y la histeroepilepsia. Por el Dr. José Incollá. Tesis del doctorado en medicina, Universidad de Buenos Aires, Facultad de ciencias médicas. Paper. Pp. 65. Buenos Aires, 1944.

This thesis for a degree in medicine reviews the diverse opinions of some forty-six authors who have discussed the problems of epilepsy, hysteria or hysteroepilepsy. The author gives case histories of 11 patients with epilepsy and 3 with hysteroepilepsy, the latter comprising the number encountered in a group of 105 patients diagnosed as epileptic.

Microbes That Cripple. By T. Arthur Turner. Written and Illustrated under the direction of Edward L. Compere, M.D. Cloth. Price, $2.50. Pp. 241, with illustrations. Elyria, Ohio: National Society for Crippled Children, Inc., 1944.

In conception, organization, execution and production this book is an outstanding contribution to the literature in medicine for the lay reader. It is definitely conceived as a treatise in a limited field of bacteriology as indicated by its title, "Microbes That Cripple," and takes in, therefore, the tubercle bacilli, the spirochete, poliomyelitis and other viruses, the hemolytic streptococcus and infectious agents such as gonococci, typhoid bacilli, pneumococci and meningococci. More limited mention is made of occasional cripplers such as measles, whooping cough and influenza. The story of chemotherapy is briefly told, and there is an outline on public health, health education and public health and disease in wartime.

The organization of the book is in thirteen chapters, of which the first is introductory. The second is a broad outline of "the world of microbes." The third has to do with immunity and the fourth with the human body and how infection can cripple it. Then follow specific chapters dealing with the various organisms. The closing chapter is on chemotherapy and public hygiene, and then there are an especially good glossary, an excellent bibliography and an adequate index.

Execution of the idea is excellent by reason of concise and sprightly writing and a flair for putting scientific material into easily understood English, which is exceptional among writers for the public. A typical example is the author's designation of the coccus group of organisms "The Berry (Alias Cocci) Family," "Bacilli—The Little Sticks," and the flagellated organisms, described as "Microbes with Oars."

Further to illuminate the manuscript is liberal use of exceptionally fine artwork, in which a number of technics are used, including photography, wash-drawings in color, pen and ink drawings, and pictograph charts, combinations of pen and ink with wash in pictograph charts, cartoons and stylized diagrams. Illustrations appear so frequently that it is difficult to turn more than two pages without finding illustrative matter, which is always clear, often striking and not infrequently amusing as well.

Finally, production is worthy of the excellence of the conception, organization and execution of this book. Good paper, large type, generous margins and clever arrangements make this a book which any one might be proud to have in his library.

An Introduction to Somatic Methods of Treatment in Psychiatry. By William Sargant, M.A., M.B., M.R.C.P., Medical Officer, Maudsley Hospital, London, and Eliot Slater, M.A., M.D., M.R.C.P., Medical Officer, Maudsley Hospital, London. Cloth. Price, $2.50. Pp. 171, with 1 illustration. Baltimore: William Wood & Company, 1944.

Although the authors are well known in the field of English neuropsychiatry, this book leaves the interviewer somewhat confused as to its purpose. They are apparently interested in setting forth positive and aggressive methods of psychiatric treatment. However, one could easily quarrel with their premise that most of the advances in psychiatric therapy have been along somatic lines. This is set forth in a long introduction describing the "constitutional approach," emphasizing biologic rather than experimental factors operating in the development of behavior disorders. While they pay some lip service to a monistic approach, they are definitely dualistic in their attitudes and adhere to archaic concepts of psychophysical parallelism. Thus we find adjunctive therapy set up as etiologic although the authors admit the empirical nature of most of the methods used. They even go so far as to describe them as "therapeutic tricks," as in the use of insulin in the treatment of schizophrenic disorders. There are chapters on supposedly specific treatment by drugs, convulsions, diet, pyrexial agents and surgery. Whenever psychotherapy is mentioned it would appear to be dispensed in the same direct positive and even aggressive manner. There is no bibliography; and, although the descriptions of technic are detailed, the beginner, for whom this book was supposedly written, would not find them complete enough to be used as a sole source of reference. The conclusion reached is that the authors seem to feel a great need to make psychiatry "respectable." When this is done by aping traditional medical approaches nothing new or worth while is added.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PENICILLIN FOR SYPHILIS

To the Editor:—I have a patient with a slight touch of recurrent syphilis. He had fairly steady treatment for one and a half years consisting of neoarsphenamine for three months followed by bismuth for three months. Following this his Wassermann reaction on three occasions was negative. A Kahn test several weeks ago gave a 4 plus reaction. He was anxious to try penicillin and was able to pay for it, so he was given 2,000,000 units: 15,000 units intramuscularly every two hours. Should arsenic and bismuth be continued a year or more or should we wait six months or so to see what his serologic reaction indicates?

M.D., Tennessee.

ANSWER.—The treatment of syphilis with penicillin is at the moment entirely in the experimental stage. Whether 2,000,000 units of penicillin given as described would be effective treatment for the patient in question cannot be determined without full and complete data as to what the correspondent means by "a slight touch of recurrent syphilis." Has the patient's spinal fluid ever been tested and, if so, with what results? Does he now show any clinical evidence of syphilis and, if so, of what sort? What were the blood serologic findings on a quantitative rather than a qualitative basis? Since under any circumstances the penicillin given must be regarded as experimental, the decision as to whether to continue with a year or more of further chemotherapy or to wait six months to see what happens is largely up to the patient, provided he is properly advised on the basis of full information by his physician. It cannot be too strongly emphasized that "4 plus" blood tests viewed as isolated phenomena are by no means the determining factor in the treatment of a patient with "a slight touch of syphilis."

HYDROCEPHALUS OR SUBDURAL HEMATOMA

To the Editor:—A boy aged 17 months has an internal hydrocephalus, the blockage probably being in the aqueduct of Sylvius. He does not walk or talk as yet and except for occasional slight vomiting and slight rises in temperature appears to be in good health. At birth his head was of normal size and shape, the changes gradually occurring after about the third month. What chance has he that a spontaneous arrest might happen? Is there any recommended treatment in the meantime? Is early intervention advised, such as an attempt to locate and remove the blockage?

M.D., Illinois.

ANSWER.—In any enlargement of the head developing about the third month after birth, the first indication is to determine the presence or absence of a subdural hematoma. This can be done by aspirating from the subdural space either through the lateral angles of the anterior fontanel or through the coronal suture. If a subdural hematoma is present it should be evacuated surgically. If it is not, and the condition is an obstructive hydrocephalus as postulated here, then one would have to know the severity of the condition and the rapidity of its progress to determine the advisability of surgical intervention. Surgical treatment of hydrocephalus in infants, whether it is of the obstructive or of the communicating type, is not satisfactory. Obstruction of the aqueduct of Sylvius can be treated either by a third ventriculostomy or by a Torkildsen operation in which a catheter is passed from the lateral ventricle to the cisterna magna extracranially. Some cases of hydrocephalus do undergo spontaneous arrest. The percentage of this happening could be determined only if additional details were known. It would be wisest to have the child examined by a competent neurologic surgeon, who could best determine the course to follow in the future.

VITAMIN K AND BILE SALTS IN HEPATOMEGALY

To the Editor:—Is the daily administration of 1 to 6 mg. of vitamin K combined with bile salts of value in relieving congestion of the enlarged cirrhotic liver which is due to long standing congestive heart failure?

M.D., Indiana.

ANSWER.—Clinical or experimental evidence leading to the expectation that the administration of bile salts combined with vitamin K would have any effect in reducing a hepatomegaly secondary to heart failure has not been found. Vitamin K is known to be necessary to the proper formation of prothrombin and, since the naturally occurring vitamin is fat soluble, bile salts are necessary for its absorption

ASPIRATION OF SECRETIONS DURING LUNG SURGERY

To the Editor:—Reports on pneumonectomy and lobectomy for tuberculosis (Overholt, R. H., and Wilson, N. J.: Am. Rev. Tuberc. 51: 18 [Jan.] 1945) stress the fact that contralateral spread of infection remains the greatest hazard the surgeon has to face. The same problem exists in resection for bronchiectasis and lung abscess, perhaps to a lesser degree. Presumably the spread of infection occurs as the result of transbronchial aspiration of pus expressed from the diseased lung by the surgeon's manipulation while the patient has a depressed or absent cough reflex due to the anesthesia. Could this be prevented by introducing, prior to operation, a bronchospirometer tube of the type used by physiologists in measuring the function of the separate lungs? As I understand it, these tubes have a cuff which can be inflated to seal off the separate major bronchi. This should prevent the transtracheal passage of pus; pus accumulating in the trachea could be aspirated before the bronchospirometer tube is removed. The tube could serve for administration of anesthesia, the anesthesia to be given endobronchially instead of endotracheally. This seems like such an obvious notion that I suppose it has been tried. If so, how did it work out? If it hasn't been tried, would it work?

Winsor Chase Schmidt, M.D., Rye, N. Y.

ANSWER.—Various arrangements of inflatable balloons around intratracheal or intrabronchial anesthesia tubes have been used but have largely been abandoned for one or more of the following reasons, some of which are theoretical: 1. The difficulty of placing the balloon or balloons exactly where they must be placed in order to accomplish their purpose is great, as are the dangers of misplaced balloons. 2. The anesthesia tube used for intrabronchial intubation of the lung not being operated on is too small to permit the free passage of an aspirating catheter of sufficient size to remove thick secretions. Direct suction on the anesthesia tube while the bronchial lumen around the tube is completely occluded by a balloon tends to empty the lung of air and produce acute atelectasis, which might be quickly fatal. 3. A single balloon used to occlude the lowermost trachea and the proximal ends of both main bronchi (the anesthesia tube being placed in the bronchus of the lung not being operated on) may bulge into the bronchus that is to be divided during a total pneumonectomy and be cut when the bronchus is divided, thereby exposing the bronchi of the opposite lung to being suddenly flooded by the secretions that had been dammed back while the balloon was intact. Apart from the possibility of this accident, a slight accidental upward displacement of the balloon at any time before the lung has been removed would result in the aspiration of the infectious secretions from the diseased into the undiseased lung. 4. When two balloons and two catheters are used, as for bronchospirometry determinations, one catheter and one balloon are introduced into a main bronchus; the other catheter ends in the lower trachea, and both catheters are surrounded by a balloon which is used to occlude the trachea. The lung to be removed is the one in which the intrabronchial catheter and balloon have not been placed. The tube ending in the trachea is too small for the passage of an aspirating catheter and, as this tube, which is surrounded by the inflated balloon, cannot be moved about, direct suction on it removes only those secretions that happen to lie at its orifice; therefore some secretions almost inevitably collect in the lowermost trachea proximal to the sutured bronchial stump and these secretions may be aspirated into the remaining lung after the intrabronchial balloon has been deflated. The double tube, double balloon apparatus can be used only for a right sided pneumonectomy because, if the anesthesia tube and balloon should be introduced into the right bronchus the balloon would occlude the upper lobe bronchial orifice, which arises just below the level of the bifurcation of the trachea (the left upper lobe bronchus arises about 3 cm. below the bifurcation). If the intrabronchial tube should be introduced into the bronchus of the lung (either left or right) to be removed while anesthesia was maintained by means of a separate intratracheal tube without a balloon, the intrabronchial tube and its surrounding balloon would be divided when the bronchus was divided after a clamp had been placed distal to the site of intended division; such a maneuver would prevent the flooding of the trachea and opposite lung by secretions from the diseased lung. The occlusion of the bronchi of the diseased lung would, however, prevent the deflation of the lung that is necessary in order to permit the surgeon to reach the hilar structures, unless the air in the lung was rapidly absorbed by the blood. 5. With regard to lobectomy, the anatomic arrangement of the lobar bronchial orifices in relation to the main bronchi is such that a balloon cannot be placed so as to block the secretions from one lobe without the balloon's occupying the part of the bronchus that should be surgically divided. If, in preparation for removal of the right lower lobe, the balloon should be placed in the intermediate bronchus proximal to the apical bronchus of the lower lobe, infectious secretions from the lower lobe would be free to pass into the middle lobe. If both the lower and middle lobes are to be removed, the balloon should not be placed in the intermediate bronchus because this should be divided just

distal to the upper lobe orifice. 6. Miscellaneous objections to the use of an inflated balloon include (*a*) accidental rupture of the balloon followed by flooding of the trachea and aspiration into the undiseased lung, (*b*) rupture of the trachea or a bronchus by the inflated balloon and (*c*) the formation of an obstructing false membrane on the tracheal or bronchial mucosa as a result of the prolonged pressure by the inflated balloon, this danger being especially great in children.

Because of the many objections to attempts to prevent aspiration of infectious secretions into undiseased portions of the lung or lungs by means of inflated balloons, the great majority of thoracic surgeons and anesthetists now use a simple intratracheal tube through which a sufficiently large catheter can be introduced for the aspiration of secretions from the trachea and bronchi. The placing of the patient in the Trendelenburg position has an important influence in causing secretions that are not reached by the aspirating catheter to flow by gravity to the pharynx, passing between the intratracheal tube and the larynx.

ERYTHEMA MULTIFORME BULLOSUM

To the Editor:—A white woman aged 45 has had erythema multiforme bullosum for seventeen years. The bullae appear on the feet and legs and are especially prevalent in the mouth. At times it becomes impossible for her to talk or eat because of the soreness of the mouth. All symptoms are promptly relieved for three months by a single injection of arsenicals. However, she has developed a great sensitivity to all arsenicals with shock-like symptoms, numbness of the extremities, projectile vomiting and substernal pain. Arsenicals used throughout the seventeen years have included arsphenamine, neoarsphenamine, oxophenarsine hydrochloride and bismarsen. Fowler's solution in dosage more than 2 drops causes nausea. Can you give me any suggestions as to alternative treatment or methods of desensitizing to arsenicals?

M.D., Wisconsin.

ANSWER.—If this patient, who has evidently developed a sensitization to arsenicals, has not had any calcium, it would be well worth trying. Although the bullous form of erythema multiforme is often more obstinate than the usual type, calcium intravenously in the form of the calcium gluconate or calcium levulinate is often helpful. In numerous instances the use of calcium in the early stages has apparently aborted the attack of erythema multiforme and lessened the frequency of attacks. This woman might be given an intravenous injection of calcium at the first sign of symptoms. This can, of course, be repeated daily three or four times if it seems advisable. There is no satisfactory method of desensitization to arsenicals. The cause of an erythema multiforme bullosum is not known, and calcium, like arsenic, has been found empirically to be useful in certain cases.

HEAT TREATMENT OF ADHESIONS—DRY AND MOIST HEAT

To the Editor:—In a patient with postoperative intraperitoneal adhesions when it is desirable to apply heat once daily over a period of months, I have been accustomed to order a hot moist abdominal pack, with an overlying hot pad, for an hour or so nightly; this is a cumbersome procedure. Do the authorities think that dry heat from an infra-red lamp or from any other convenient form of dry heat is as effective as is moist heat?

M.D., Missouri.

ANSWER.—Satisfactory evidence is not available that any form of heat applied to the abdomen is of value in the treatment of postoperative intraperitoneal adhesions.

The heat obtained from infra-red lamps, radiant heat lamps and electrically heated pads is not the same as that obtained from hot compresses. Clinically the results frequently differ, the hot compress proving to be more effective than the "dry" methods of heating in the treatment of some conditions. Lamps produce heat which is conversive, convective and conductive. The surface of the skin to which the radiation is applied is exposed to the motion of the air of the room. The heat produced by hot compresses is conductive—and the surface to which it is applied is protected from environmental influences.

DYSMENORRHEA WITH CLOTS

To the Editor:—A woman aged 25, single, has suffered severe dysmenorrhea associated with scanty flow. The menstrual flow consists largely of both large and small clots. A headache of a migraine nature usually is present. How can these large clots be prevented?

M.D., Illinois.

ANSWER.—There is no satisfactory way of preventing clot formation during the menses except by curettement, and even this procedure is far from being a specific remedy. Nevertheless if the curettement is preceded by a thorough dilation of the cervix it may not only prevent the formation of clots but also relieve the patient's dysmenorrhea, at least temporarily.

TOXICITY OF CALCIUM

To the Editor:—Is there a good clinical basis for the warning that calcium lactate is contraindicated in old age? This warning appears on a label and refers to compressed tablets of calcium lactate 10 grains (0.65 Gm.). Is there a definite contraindication for a high calcium diet for the aged? If so, what about attributing the longevity of certain Bulgarian or Balkan peoples to their consuming liberal amounts of soured milk, which, along with acidophilus bacilli, is rich in calcium?

Frederick G. Murray, M.D., Cedar Rapids, Iowa.

ANSWER.—The toxic effects from calcium differ according to the route of administration. Intravenous administration should be performed with care, as large or rapid injections may cause acute lowering of the blood pressure and paralysis of the heart and respiration. Such an effect would be more serious in older people. In view of its synergism with digitalis, it is dangerous to inject calcium solutions into digitalized patients. Winkler has pointed out the possibility that a heart predisposed to ventricular fibrillation may respond in this way in an occasional case to an ordinarily innocuous concentration of calcium. Sollmann states that the toxic effects of calcium salts occur only with parenteral administration. The absorption of orally administered calcium depends on the p_H of the contents of the gastrointestinal tract. Serious elevation of serum calcium does not occur even under the most favorable conditions for absorption unless an excess of vitamin D or parathyroid hormone is present. Overdosage of these may raise the serum calcium to abnormally high levels and result in metastatic calcification and other toxic effects. The same factors are involved in the use of a high calcium diet. Robertson concludes that overdosage of calcium by diet alone cannot exist in the normal adult population, since excess calcium is excreted in the feces. His findings indicate no difference in calcium balance in older people as compared to younger adults. Laboratory experiments on rats show a slight increase in longevity from a lifetime limited increase in the calcium content of the diet. The possible clinical significance of these experiments has not been determined.

There are no satisfactorily controlled studies which prove that sour milk or "acidophilus milk" has a favorable effect on longevity. The favorable clinical results (gastrointestinal) reported for "acidophilus milk" have been obtained only when living organisms have been present. Thus, it is unlikely that the beneficial effects usually claimed are related to the calcium content.

GLASS AMPULES

To the Editor:—In the operation of our various clinics we have need of and use a great number of glass ampules. Observing the careless manner in which some doctors and nurses break these ampules I am wondering what effect would result if the following hypothetical conditions prevailed: If glass particles are left in the intravenous solution could they pass through a hypodermic needle of 20 gage capacity? If by chance a small particle of glass did enter the lumen of the vein and get into the circulatory system, what harmful effect might accrue? How could an insoluble particle like glass escape out of the circulation and what would be its probable final disposition? Some ampules have a constriction in the neck which simplifies smooth breakage. Others have a sloping neck which makes it practically impossible to prevent shattering of the glass. What precautions would be advisable to offset these difficulties?

M.D., Texas.

ANSWER.—There is little doubt that fine glass particles are frequently injected intravenously. The final disposition of the particles probably varies greatly. There is some evidence that the liver capillaries are smaller or less distensible than those of other parts of the body and consequently one would expect foreign bodies to be walled off in the liver tissue in most cases. Reasonable care in drawing solutions for intravenous injection into the needle should be observed, but there are no other particular precautions which can be exercised. Perhaps ampules made of plastic or glass with a plastic closure will be available at some future time. Considering the vast number of intravenous injections made with materials contained in glass ampules without evidence of harmful effect, there would seem to be little practical danger from this procedure.

TRANSIENT HYPERTENSION

THE RELATIVE PROGNOSTIC IMPORTANCE OF VARIOUS SYSTOLIC AND DIASTOLIC LEVELS

BRIGADIER GENERAL CHARLES C. HILLMAN
UNITED STATES ARMY

In the preceding paper in this series,[1] based on an analysis of the medical records of 22,741 officers of the United States Army, the significance of transient hypertension was considered in terms of the subsequent state of health and the cause of death. A comparison was made between those who exhibited temporary elevations of blood pressure and those with normal levels throughout the periods of observation. The group with transient hypertension showed a greater incidence of later sustained hypertension and higher rates for disability retirement and death with cardiovascular-renal diseases.[2] It is thus apparent that, in many persons, a temporary rise in blood pressure, even though this occurs under emotional stress, must be regarded as of consequence; it is often an early sign of disorder in the circulatory system.

In the study just mentioned, the group with transient hypertension was dealt with as a whole; there was no attempt to ascertain possible differences in the prognostic importance of various systolic and diastolic levels. To obtain data on this point seemed the next logical step in the inquiry. The results are given in the present report.

MATERIAL AND PROCEDURE

The sources of the records and the general composition of the material already have been published in detail.[3] A punch card was made for each of the 22,741 cases, so that manipulation for statistical purposes could be readily carried out. Cardiovascular-renal conditions, if present, were always tabulated as causes of retirement and death, even though not immediately responsible for either. For example, malignant disease may have been the reason for which an officer left the service; but if hypertension also was present, he was considered to have retired with this circulatory disorder. A similar procedure was followed in case of death.

In dealing with data of this sort, age is of fundamental importance. This factor has been taken into account by resorting to an analysis in terms of person-years of observation, as was described in a previous paper.[1]

For purposes of study, the subjects with transient hypertension were divided into groups according to the highest levels of blood pressure recorded during the period of observation. For the systolic, the groups were 151 to 165 and 166 to 225; for the diastolic, 91 to 100 and 101 to 150. There were no readings noted above 225 systolic and 150 diastolic. Every combination of systolic and diastolic pressure was given separate consideration so that, excluding the simultaneous occurrence of normal values for the two, there were eight categories in all. Further subdivision, by reducing the number in each group, would have lessened the value of the comparisons.

RESULTS

The fundamental results are summarized in table 4. Tables 1, 2 and 3, from which the various ratios of table 4 are derived, are reproduced merely to illustrate the method employed.

In table 1 is shown the number of person-years of observation in each age group before the occurrence of sustained hypertension, for the various degrees of transient hypertension. By far the most extensive observations pertain to the group with a normal systolic pressure and a minimal elevation of the diastolic; the least extensive are in the group with a high systolic and a normal diastolic. The latter combination, as might be expected, is relatively uncommon. The distribution in the other groups is fairly even. Similar distributions of person-years were tabulated for each group before the occurrence of retirement or death. In this table the length of the calculated overall period of observation is some 5 per cent larger than that indicated in table 1 because it includes the time from the onset of permanent hypertension to retirement or death. Although the table is not shown, it was used in the derivation of table 4.

This is the third in a series of papers dealing with "Studies of Blood Pressure in Army Officers."

Dr. John W. Fertig, professor of biostatistics, Columbia University College of Physicians and Surgeons, aided in the analysis and preparation of the material for final presentation.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University.

2. By transient hypertension is meant a reading over 150 mm. of mercury systolic or 90 diastolic which is followed, on any particular examination or at a later examination, by a reading below these levels. The highest systolic and diastolic readings obtained in any one of a series, taken at a given examination, were recorded. Sustained hypertension is taken to mean a reading of over 150 systolic or 90 diastolic, persisting throughout an examination and not followed in subsequent examinations by lower levels.

3. Hillman, C. C.; Levy, R. L.; Stroud, W. D., and White, P. D.: Studies of Blood Pressure in Army Officers: Observations Based on an Analysis of the Medical Records of 22,741 Officers of the United States Army, J. A. M. A. 125:699 (July 8) 1944.

In table 2 are given the rates, in the subjects without transient hypertension, for the later occurrence of sustained hypertension, and of retirement and death with cardiovascular-renal diseases. These figures are taken from tables 2, 3 and 5 in an earlier paper.[1]

In table 3 appears the comparison, by age and for various degrees of transient hypertension, between the observed and expected number of cases of later sustained hypertension, of retirements and of deaths with cardiovascular-renal diseases. The expected number of cases was obtained by applying, at the various ages, the normal rates shown in table 2 to the corresponding age distribution of person-years, such as given in table 1. In each of the three categories of occurrences, the total observed number of cases exceeded that expected; and with only one exception, this relationship held for every combination of systolic and diastolic pressure.

In table 4 are shown the ratios for the observed to the expected number of cases of later sustained hypertension, as well as for retirements and deaths, by various levels of systolic and diastolic blood pressure. These ratios were calculated from the figures given in table 3.

The ratios for deaths with cardiovascular-renal diseases are, with one exception, all greater than unity. But they are not all significantly greater, nor do they show differences between the various levels of pressure, either for the systolic or for the diastolic. It is thus not clearly demonstrated that every transient elevation of blood pressure above the normal is important from the point of view of death with a circulatory disorder.

COMMENT

Very few attempts have been made to appraise the relative importance of various degrees of transient hypertension. In fact, only two pertinent references have been found. On the basis of the experience of the Prudential Insurance Company of America, MacKenzie and Shepherd[4] in 1937 stated that a systolic pressure of 150 mm. or more in the past required a rating, even though later pressures were normal; and a record of a previous systolic of 165 or over, with moderate elevation on subsequent examination, required a substantial rating or rejection. No similar information on diastolic pressures was available.

In 1940 Hines[5] reported the results of a study of 1,522 patients at the Mayo Clinic, of whom some were checked ten and some twenty years later. Only 243 (4.4 per cent) had blood pressure readings on the first examination of more than 145 mm. systolic and 90 diastolic. This initial elevation was assumed to be due to nervousness, since there was no evidence of vascular or renal disease. The following conclusions were drawn: Transient elevations of blood pressure above

TABLE 1.—*Person-Years Observed Before Occurrence of Sustained Hypertension, by Age, for Various Degrees of Transient Hypertension*

	Degree of Transient Hypertension, Mm. Hg

Total	25,493	3,591	2,097	5,728	3,428	511	2,305	4,237

With respect to the later development of sustained hypertension, it appears that all levels of transient hypertension, whether involving the systolic or diastolic or both, are relevant. The ratios for all levels of the systolic are so nearly alike that no emphasis can be placed on any one of them. In general, the ratio does not change significantly with a change in the systolic level, provided the diastolic remains constant. On the other hand, as the diastolic level rises while the systolic remains constant, the ratio does increase significantly. On closer analysis, however, it is evident that the ratios for the "90 or less" and the "91 to 100" groups do not differ from each other, but that both of these differ from the "over 100" group. The high ratio for this last group stands out prominently.

The same trends are evident in the case of retirements with cardiovascular-renal diseases. Here again, with one possible exception, every transient elevation above the normal, for both systolic and diastolic pressures, has a statistically significant ratio. After detailed analysis of the ratios, the same conclusion is reached as in the case of later sustained hypertension, namely that it is a diastolic reading above 100 which is of the greatest importance. Because of the small number of cases involved, not much attention should be given to the ratio obtained for the group 166 to 225 systolic, 90 or less diastolic.

TABLE 2.—*Rates for Sustained Hypertension, Retirements and Deaths, by Age, Among Those Without Transient Hypertension*

	Rate per Thousand Person-Years Observed		
	Later Occurrence of Sustained Hypertension	Cardiovascular-Renal	
Age, Years		Retirements	Deaths

5. Hines, E. A., Jr.: Range of Normal Blood Pressure and Subsequent Development of Hypertension: A Follow-Up Study of 1,522 Patients, J. A. M. A. 115: 271 (July 27) 1940.

140 mm. systolic or 85 diastolic are prognostic of probable subsequent hypertension (defined as above 160 systolic and 100 diastolic), the higher the original reading, the higher the incidence of subsequent hypertension; rise in the systolic pressure alone is not indicative of subsequent hypertension, 85 mm marks a critical level of the diastolic pressure as to the possible occurrence of subsequent hypertension.

TABLE 3—*Observed Number of Cases of Sustained Hypertension, and of Retirement and Death, by Various Degrees of Transient Hypertension, Compared with That Expected on the Basis of the Rates for the Group Without Transient Hypertension* *

Degree of Transient Hypertension, Mm Hg	Later Occurrence of Sustained Hypertension		Cardiovascular Renal			
			Retirements		Deaths	
	Observed	Expected	Observed	Expected	Observed	Expected

166 225 / 90 or less	14	3	12	3	2	1
166 225 / 91 100	48	16	26	19	2	4
166-225 / 101 150	139	26	87	30	20	7
Total	922	260	583	289	152	69

* The expected number of cases was obtained by applying, at the various ages, the normal rates shown in table 2 to the observed age distribution of person years, such as that given in table 1

Our own study is characterized by being based on the records of a relatively large number of persons followed over long periods of time and by the fact that annual examinations were made In addition, in all of the calculations age and the period of follow-up were taken into account by using the method of person-years For these reasons, direct comparison of our results with those so far reported by others is not feasible

Certain features merit special mention. It is clear that all levels of transient hypertension, as here defined, are significant This obtains for both the systolic and the diastolic pressure, using as indexes the later development of sustained hypertension and retirement with cardiovascular-renal diseases Of particular interest is the observation that slight degrees of elevation are important, even when the systolic level alone is involved Outstanding, however, and of the greatest significance, is a transient rise in the diastolic pressure above 100 mm, especially as far as this may be an early sign of subsequent sustained hypertension

It has already been pointed out that, in the group with transient hypertension as a whole, the death rate with cardiovascular-renal diseases was significantly higher than in the group with normal pressures. Yet no real differences were apparent between the rates pertaining to the various degrees of elevation. This may be explained in part by the relatively small number of deaths involved. But it may be due also to the unpredictable course of hypertensive vascular disease, once this has been established. Prognostic criteria, except in the advanced stages, are uncertain and frequently deceptive. So too the degree of transient hypertension does not serve to foretell the severity and extent of the condition which eventually is a cause of death.

SUMMARY AND CONCLUSIONS

1. In an earlier paper, based on an analysis of the medical records of 22,741 officers of the United States Army, it was shown that in the group with transient hypertension there was a greater incidence of later sustained hypertension and there were higher rates for retirement and for death with cardiovascular-renal diseases Using the same material and indexes, the present study was designed to demonstrate possible differences in the prognostic importance of various systolic and diastolic levels of transient hypertension.

2. With respect to the later development of sustained hypertension and retirement with cardiovascular-renal diseases, all levels of transient hypertension, both systolic and diastolic, were significant Of particular interest was the observation that slight degrees of elevation were important, even when the systolic level alone was involved Of the greatest significance was a transient rise in diastolic pressure above 100 mm, especially as an early sign of subsequent sustained hypertension.

3. No significant differences were apparent between the various degrees of transient hypertension in relation to the death rates with cardiovascular-renal diseases So, as is true for many other prognostic criteria applied to these conditions, the height of a temporary rise in blood pressure does not appear to foretell the severity or extent of the lesions which eventually are a cause of death.

4. The data given lend support to the view that transient elevations of blood pressure, above the upper range of normal, often represent an early stage of hypertensive vascular disease.

THE USE OF HUMAN IMMUNE SERUM GLOBULIN (GAMMA GLOBULIN)

IN INFECTIOUS (EPIDEMIC) HEPATITIS IN THE MEDITERRANEAN THEATER OF OPERATIONS

I. STUDIES ON PROPHYLAXIS IN TWO EPIDEMICS OF INFECTIOUS HEPATITIS

CAPTAIN SYDNEY S. GELLIS
MEDICAL CORPS, ARMY OF THE UNITED STATES
JOSEPH STOKES JR., M.D.
PHILADELPHIA
MAJOR GEORGE M. BROTHER
MAJOR WILLIAM M. HALL
COLONEL HUGH R. GILMORE
MAJOR EMIL BEYER
MEDICAL CORPS, ARMY OF THE UNITED STATES
CAPTAIN RICHARD A. MORRISSEY
SANITARY CORPS, UNITED STATES ARMY

Prior to the report of Stokes and Neefe [1] indicating the value of gamma globulin from pooled human plasma in the prevention and attenuation of infectious (epidemic) hepatitis, no method of control of outbreaks of this disease had been available. The extensive literature on infectious (epidemic) hepatitis that has accumulated in the past several years bears witness to the widespread occurrence of this disease both in the armed services and among civilian populations. The lengthy period of convalescence following infectious hepatitis has made it of prime importance to the armed services of all the United Nations.

On the basis of the report of Stokes and Neefe and on the recommendation of the Surgeon General, U. S. Army, and at the invitation of the Chief Surgeon and the Commanding General, Mediterranean Theater of Operations, U. S. Army, to two of the authors of this present report, field studies on the effectiveness of gamma globulin [2] in the prevention of infectious hepatitis were conducted during the fall of 1944 and the winter of 1944-1945 in the Mediterranean Theater of Operations, U. S. Army. A heavy bombardment group with a relatively high incidence of infectious hepatitis was chosen at the suggestion of Col. Marion H. Barker, M. C., and Lieut. Col. Ross Gauld, M. C., and with the concurrence of Col. William S. Stone, M. C., and Col. Otis Benson, M. C., for the initial testing of the gamma globulin.

This bombardment group consisted of four squadrons and headquarters personnel. The four squadrons were of approximately equal size (each about 500 men) and were quartered around the same air field. Despite the fact that the study was begun late in the course of the outbreak of the disease, the group appeared highly suitable for investigation since its location was fixed and its rate of replacement was low. The number of cases of hepatitis with jaundice in the various squadrons of this group up to the time of injection of globulin is summarized in table 1.[3]

Squadrons A and C were chosen for globulin administration, while Squadrons B and D served as controls. Because of its large number of key personnel, the headquarters group also received globulin. As a result of the inclusion of the headquarters group, the number injected exceeded the number of controls by over 100 men.

TABLE 1.—*Cases of Hepatitis with Jaundice Previous to Globulin Injections*

	Head quarters	Squadron A	B	C	D
Aug. 15 to Sept. 30	2	23	32	6	14
Oct. 1 to Oct. 31	1	13	19	9	9
Nov. 1 to Nov. 27	1	20	30	4	12
Total	4	56	81	19	35

Over a two day period, beginning on Nov. 27, 1944, a total of 10 cc. of globulin was given intramuscularly in the buttocks to each man in the injected squadrons. A few men, however, failed to receive the injections. The 10 cc. dosage was chosen as the largest that could be administered without adversely affecting full duty status of the men. No reactions followed administration of the globulin except for an occasional mild burning sensation at the site of injection.

Cases of hepatitis without jaundice were not included in the evaluation of the effectiveness of globulin. This form of hepatitis may be confused with various other diseases, and it was felt that by limiting the study to hepatitis with jaundice the conditions of the experiment were made more exacting.

In table 2 are recorded the cases of hepatitis with jaundice which occurred in the period from December 3 to January 26, following the date of injection. Cases which occurred between November 27 and December 1944 are not included, because of previous experience which had indicated that globulin when administered very late in the incubation period failed to prevent completely the development of the disease.

Thus in the injected squadrons 3 cases of hepatitis with jaundice occurred following the administration of globulin. In 2 of the 3 cases globulin had not been administered. The third case, with evidence of scleral icterus only, occurred nine days following the injection of globulin. In the same period 25 cases of hepatitis with jaundice occurred in the control squadrons.

TABLE 2.—*Cases of Hepatitis with Jaundice Occurring from Dec. 3, 1944 to Jan. 26, 1945 in Injected Men and Controls*

* Failed to receive globulin

This work was carried out under the direction of the Commission on Measles and Mumps of the Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, U. S. Army.

1. Stokes, J., Jr., and Neefe, J. R.: The Prevention and Attenuation of Infectious Hepatitis by Gamma Globulin, J. A. M. A. 127:144 (Jan. 20) 1945.

2. The gamma globulin used in these studies was obtained from pools of plasma, each pool representing 3,000 to 5,000 individuals, collected by the American Red Cross and fractionated, according to the method of Cohn and his co-workers, by various biologic manufacturers. These pools were obtained originally from groups of individuals in the Eastern and Southern regions of the United States.

3. The selection of squadrons for the injected and control groups was based on the reports of the total number of cases of hepatitis. When it was possible later to examine more complete data it was found that, while the total number of cases of hepatitis had been approximately equal in the injected and control groups previous to the time of injection, the cases of hepatitis with jaundice as indicated had not been equal. The experiment was thus weighted slightly in favor of the injected group, but not sufficiently so to account for the difference obtained.

With the extension of the disease in the Mediterranean Theater of Operations the opportunity arose to conduct a similar study in the ground forces.[4] Regiments were selected in which the disease had already started, and three groups of men from various companies of these regiments were chosen for the study. In group 1 406 men, 40 per cent of the strength of the companies forming the group, received globulin, the remaining men, 683, served as controls. In group 2 831 men, 10 per cent of the strength of the companies selected, were injected; 8,270 men remained for controls. In group 3 495 men, 25 per cent of the strength, were injected, the remaining 1,373 serving as controls Each man injected received 10 cc. of gamma globulin intramuscularly. Group 1 was then studied for twelve weeks, group 2 for seven weeks and group 3 for five weeks following the date of injection.

In table 3 are recorded the cases of hepatitis with jaundice which occurred in the three groups during the follow-up period.

The significant results obtained in the foregoing studies suggest that gamma globulin is a potent agent in the prevention of infectious hepatitis. It is impossible to draw conclusions from these studies as to the duration of immunity conferred by globulin, but the results suggest that it may be a period of at least six to eight weeks.

TABLE 3.—*Cases of Hepatitis with Jaundice Following Date of Injection with Globulin*

Group	Total Injected	Jaundice Cases	Incidence, per Cent	Total Controls	Jaundice Cases	Incidence, per Cent
1	406	4	1	683	25	3.7
2	831	3	0.4	8,270	283	3.4
3	495	2	0.4	1,373	27	2.0

COMMENT

The present studies, together with those reported previously,[1] indicate that human immune serum globulin (gamma globulin) has been effective in preventing infectious (epidemic) hepatitis with jaundice in three separate epidemics of the disease. Although the signs and symptoms of the disease in all three epidemics were similar and although two of the epidemics appeared in the Mediterranean Theater of Operations at approximately the same time, it is still possible, although not probable, that the etiologic agent in each epidemic was different. Irrespective of possible etiologic differences, it is clear that the gamma globulin was equally effective in all outbreaks of infectious hepatitis. Whether or not such globulin from large pools of blood from three to five thousand individuals is effective in prophylaxis against serum hepatitis, such as that caused by the yellow fever vaccine during the present war, is not clear and must await further experimental study.

SUMMARY

An outbreak of infectious (epidemic) hepatitis in a bombardment group based in the Mediterranean Theater of Operations and in various regiments of the ground forces in the same theater offered an opportunity to study the effectiveness of human immune serum globulin (gamma globulin) in the prevention of this disease.

The results of these two field studies support the findings of Stokes and Neefe that the gamma globulin is a potent agent in the prevention of such hepatitis and suggest that the globulin confers a period of passive immunity of at least six to eight weeks.

4 Col. Charles O Bruce, M C., and Lieut Col Ross Gauld, M. C., assisted in this investigation.

AN EPIDEMIC OF INFECTIOUS HEPATITIS APPARENTLY DUE TO A WATER BORNE AGENT

EPIDEMIOLOGIC OBSERVATIONS AND TRANSMISSION EXPERIMENTS IN HUMAN VOLUNTEERS

CAPTAIN JOHN R NEEFE
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
JOSEPH STOKES JR., M D.
PHILADELPHIA

The control of infectious (epidemic) hepatitis, the only pandemic disease of the present war, has been seriously handicapped by the lack of any conclusive evidence concerning its method or methods of transmission. In our recent report on the prevention and attenuation of infectious hepatitis by gamma globulin [1] there was brief mention of the epidemic in which the globulin was tested. The epidemiologic factors involved in that epidemic also were investigated, and subsequently transmission experiments in human volunteers, using materials obtained from the patients and the camp, were conducted in order to supplement and confirm the epidemiologic observations. The results of these investigations have provided information concerning the sources of the causative agent and at least one of the methods responsible for its transmission.

I. THE EPIDEMIC

The Camp.—The epidemic occurred in a summer camp for boys and girls located in an isolated area in the Pocono Mountains near Philadelphia. The boys' and girls' sections of the camp were not separated by any physical boundary but were relatively independent units because each section had its own office, kitchen, dining room, infirmary, staff and activities. However, considerable intermingling between some of the members of the two groups resulted from mixed social and athletic activities. The members of the camp group were all of homogeneous racial origin (Jewish) and came from many cities and towns in a number of different states. With few exceptions all

Read in abbreviated form at the annual meeting of the American Epidemiological Society in Washington, D. C., April 7, 1945.

From the Department of Pediatrics, University of Pennsylvania School of Medicine and the Hospital of the University of Pennsylvania.

This investigation was conducted under the Commission on Measles and Mumps, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, U. S Army, Washington, D. C.

This investigation was made possible through the continued assistance and cooperation of the owners of the camp. Dr. I. E. Brownstein, Dr. Simon Forman and Dr. S. S. Mintz supplied information concerning the early phases of the epidemic and assistance in the collection of specimens Members of the camp group and the many family physicians provided case data, obtained and delivered specimens and reported new cases among the camp group or their contacts. Other persons assisting in this part of the investigation included Miss Marion Thatcher, Miss Ruth Kennedy, Dr. James Woods, Dr Robert Mayock and many members of Civilian Public Service Unit No 140, Philadelphia.

The use of human volunteers for the transmission experiments was made possible by the cooperation of the administrative staffs of Selective Service (Camp Operations Division), the National Service Board for Religious Objectors, the American Friends Service Committee, the Philadelphia State Hospital and the New Jersey State Hospital Members of Civilian Public Service Unit No 140, Philadelphia, volunteered as subjects for these experiments. Many other members of C. P. S Unit No 140 assisted in analysis of the data, prepared the illustrations and assisted in many other ways in the conduct of parts of this investigation John G Reinhold, Ph D, principal biochemist, Philadelphia General Hospital, gave advice, supervised the biochemical studies and prepared some of the materials used in the experiments Mr Charles Ming, Capt Sydney S. Gellis, M. C, A. U S, and Dr. Francis D. W Lukens also assisted in the conduct of some phases of the investigation. Cooperation and assistance were given by the members of our laboratory staffs (Miss Dorothy Feinberg, Miss Arvilla Howley, Mrs Jean Flick, Mrs Mary Ming and Miss Catherine Fowler), Miss Dorothy Lanning and Miss Anne Messer of the biochemical laboratory of the Philadelphia General Hospital and members of the laboratory staff of the New Jersey State Hospital The bacteriologic divisions of the laboratory of the New Jersey State Hospital and of the William Pepper Laboratories of Clinical Medicine of the Hospital of the University of Pennsylvania made the bacteriologic studies

1. Stokes, J., Jr., and Neefe, J R The Prevention and Attenuation of Infectious Hepatitis by Gamma Globulin, J. A. M. A. **127**: 144 (Jan. 20) 1945.

arrived at the camp on or about the opening date of June 30, 1944. After that time there was relatively little change in the camp population until the onset of the epidemic, although many friends and relatives visited. Prior to the epidemic, campers and counselors in the boys' and girls' sections numbered approximately 275 and 220 respectively. The campers ranged from 3 to 17 and the counselors from 17 to 30 years of age. Approximately 78 other persons, most of them under 40 years of age, completed the camp group.

Collection of Data.—For the sake of convenience in description of time relationships, the weeks following the opening date of camp have been numbered in sequence. We were notified [2] of the existence of this epidemic during the 7th week of the season, approximately two weeks after the start of the epidemic. Case data at that time were obtained from the records of the camp physicians and directors. Subsequent case data were obtained from the same source and by questionnaires which were sent to all members of the camp group. As many of them developed the disease after returning the first questionnaire and after they had returned home, a second set of questionnaires was sent to the entire group at a later date. The response to both sets of questionnaires was excellent. Since many of the group were from Philadelphia, additional data were obtained by telephone, from personal visits and from family physicians. When necessary, information was obtained by telephone concerning persons in other cities and towns

Course of the Epidemic.—Three days after the opening of the camp (1st week) a woman (patient 1) aged 21, working in the office of the girls' section and living in cabin A, became ill with infectious hepatitis. During the 3d week an outbreak of "gastrointestinal upsets" occurred in the girls' section. As these were transient and usually did not require admission to the infirmary, complete records were not available. However, the section physician estimated that 25 to 30 per cent of the girls were involved, and the outbreak was of sufficient magnitude to lead him to institute special dietary measures for the entire female group. The outstanding symptom was nausea, headache was common, and vomiting and fever were present in some cases. Diarrhea was infrequent. Recovery occurred in twenty-four to forty-eight hours. A similar outbreak occurred during the 4th and 5th weeks in the boys' section.

During the 4th week and three and one-half weeks after the onset of hepatitis in the office worker, a female counselor (patient 2) developed the disease. This person also resided in cabin A and was closely exposed to case 1 during the 1st week. In the 5th week 2 more persons in the female group developed hepatitis. These persons lived in different cabins and had no unusual exposure to the first 2 cases. The epidemic nature of the disease became apparent during the 6th week, when 40 persons in the female group and 13 in the male group became ill with hepatitis. In both groups, campers and counselors living in different cabins were involved and the cases in the male group had had no recognized exposure to the early cases in the female group. In the following week the incidence in the male group rose sharply and that in the female group decreased. Additional cases continued to appear in the female and male groups until the end of the 12th and 13th weeks respectively, at which time the epidemic abruptly terminated.

TABLE 1.—*Total Incidence of Hepatitis at the Camp*

Group	Number	Hepatitis: With Overt Jaundice No.	%	Without Overt Jaundice No.	%	Total No.	%
Female group	292	139	53	43	16	182	69
Male group	280	116	38	52	17	168	55
Both groups	572	255	44	95	17	350	61

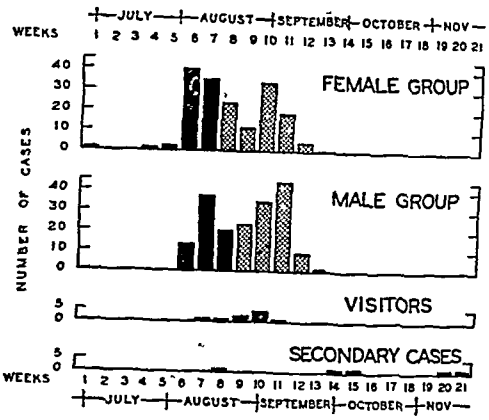

Chart 1.—Weekly incidence of hepatitis. The female and male groups include only those persons who resided in the female and male sections of the camp respectively. The group designated as visitors includes the persons who developed hepatitis after visiting the camp for only short periods. The group designated as secondary cases includes only those persons who had not visited the camp but developed hepatitis after exposure to infected persons from the camp. In respect to the female and male groups, solid bars have been used to indicate the number of persons developing the disease while at the camp, the cross hatched bars indicating the number developing their initial symptoms after leaving the camp. Although indicated by solid bars, in all of the visitors and secondary cases the disease developed away from the camp.

In table 1 the total incidence of hepatitis for the female and male groups is shown in terms of the number of cases and the percentage of the total group involved. The cases of hepatitis have been divided on the same basis according to the presence or absence of overt jaundice. The data show that the female group had the highest incidence of hepatitis even though the number of persons in this group was smaller than that in the male group. In respect to the combined groups, 350 (61 per cent) of the 572 persons contracted hepatitis during the thirteen weeks of the epidemic. Of the 350 cases, 344 occurred between the 6th and 12th weeks. None of these patients died. Forty-four per cent (255) of the total group of 572 persons developed overt jaundice, and 17 per cent (95) had hepatitis without overt jaundice. Thus 27 per cent of the hepatitis cases did not develop overt jaundice, giving a ratio of 2.7 to 1 of jaundiced to nonjaundiced cases.

As shown in chart 1, the weekly incidence curves of both the male and female groups showed two peaks. The highest weekly incidence in the female group is shown by the primary peak in the 6th week. The lower secondary peak occurred in the 10th week. The primary peak in the male group was in the 7th week. However, the highest weekly incidence in this group is reflected by the high secondary peak in the 11th week. Thus the majority of cases in the female group occurred during the early weeks of the epidemic period, whereas the majority in the male group occurred during the later weeks.

At least 9 persons who visited the camp for periods of two hours to several days at some time during the first six weeks developed hepatitis after three to six weeks. The total number of visitors to the camp is not known.

2. Dr. Charles L. Brown, professor of medicine and head of the Department of Medicine, Temple University School of Medicine, first was called in consultation by the camp directors for advice in connection with this epidemic. Dr. Brown, knowing of the interest of the Commission on Measles and Mumps in this disease, notified the director of the commission (J. S. Jr.) of the existence of the epidemic and of the desire of the camp directors for its investigation.

Since all of the girl campers and most of their counselors had returned to their homes by the end of the 7th week, and the entire camp group by the end of the 9th week, chart 1 shows that approximately 175 persons developed the disease at home after leaving camp. In addition, approximately 175 others in various stages of the disease had returned home with hepatitis. Follow-up inquiries were made at frequent intervals for four months after the camp had closed, and all of the members of the camp group were informed of the importance of reporting secondary cases among their contacts. Of the many relatives and friends, including many children, who had not visited the camp but subsequently were in close and prolonged contact in the various homes with approximately 350 infected persons from the camp, only 5 are known to have contracted hepatitis. Four of the 5 persons were relatives who lived in houses with persons infected at the camp. The 5th was a hospital nurse who was responsible for the care of one of the boy campers during the preicteric period of his disease. Considering the large number of persons exposed, the occurrence of only 5 secondary cases suggests that the agent was not easily acquired from infected persons away from the camp.

Diagnosis.—The differential diagnosis will be discussed in more detail in a subsequent report on other observations made in relation to this epidemic.[3] Briefly, the diagnosis of the disease as infectious hepatitis was based on the following points: (1) typical clinical picture and laboratory findings of infectious hepatitis; (2) absence of previous injections of homologous blood products and no opportunities for syringe or needle transmission of agent of serum hepatitis; (3) exclusion of Weil's disease by laboratory studies, which included dark field and electron microscopic examinations of serum, guinea pig inoculations, agglutination and complement fixation tests, leukocyte counts and microscopic urine examination; (4) absence of history of ingestion of hepatotoxic drugs or exposure to chemicals; (5) demonstration that the causative agent passed through a Seitz filter.

The diagnosis of infectious hepatitis without jaundice was made in patients presenting the same symptoms and signs as those who subsequently developed overt jaundice. Liver function studies on representative cases of the nonicteric group revealed bilirubinuria, increased urobilinogenuria, positive cephalin cholesterol flocculation tests and abnormal retention of sulfobromophthalein.

II. TRANSMISSION EXPERIMENTS IN HUMAN VOLUNTEERS

The transmission experiments will be considered first because the results assist in the subsequent discussions ("Epidemiologic Observations") of the possible sources of the causative agent and its method or methods of transmission at the camp. Because all attempts to cultivate the hepatitis agent in chick embryos and tissue cultures have been unsuccessful and no animal has been found to be susceptible, the only method of determining the presence of the agent in a given material is by demonstrating the ability of that material to produce the disease in human volunteers. It has been necessary, therefore, to use human beings for the transmission experiments.

A. METHODS AND MATERIALS

Volunteers.—The men who volunteered as subjects for these experiments were all under 35 years of age and had no previous history of jaundice and no evidence of liver dysfunction detectable by history, physical examination and liver function tests.

3. Neefe, J. R., and Stokes, J. Jr.: Infectious Hepatitis: Miscellaneous Observations on an Epidemic, to be published.

Studies on Volunteers.—Each subject was studied frequently by means of the group of liver function tests described in a previous report.[4] These included quantitative determinations of the serum concentrations of total bilirubin, total protein, albumin, globulin and total and esterified cholesterol; the serum cephalin cholesterol flocculation test; the thirty minute sulfobromophthalein test (5 mg. per kilogram dose), and urine tests for bilirubin (Harrison and diazo spot tests), urobilinogen (Wallace and Diamond) and urobilin (Schlesinger). These studies were made on each volunteer at frequent intervals during a one to three month preinoculation[5] period in order to determine the physiologic variation in the response of each one to these procedures over a period of time. After inoculation, most of these tests were carried out two to more times weekly up to six months. The same studies were conducted over the same interval of time on a group of 10 control subjects. In a few cases electrophoretic studies of the serum proteins were made on serum specimens collected before and after the onset of hepatitis. During the postinoculation period, groups inoculated with different materials were isolated from one another and the usual measures to prevent cross infection were instituted.

Materials.—Serum, nasopharyngeal washings, urine and feces were collected from many persons of the camp group in various stages of hepatitis. Serum and feces were also collected from volunteers who developed hepatitis following their inoculation with certain of the aforementioned materials. All specimens were examined bacteriologically, and any that contained bacteria other than the usual flora were discarded. These materials were all frozen within one to six hours after collection and were stored at minus 5 to minus 20 C. until used. In addition to the foregoing materials, water was obtained from one of the camp wells and flies were obtained from a fly trap in the boys' section of the camp. After thawing, certain specimens were pooled prior to their administration to human volunteers. The relationship of the specimens used in each pool to the times of onset of hepatitis in the donors is given in table 2, and the methods of collection of specimens and of preparation of the pools are discussed in connection with the results of their administration to volunteers (table 3).

TABLE 2.—*Time of Collection of Specimens Used in Pools in Relation to Time of Onset of Hepatitis in Donors*

B. RESULTS

The results of administration to volunteers of serum, nasopharyngeal washings, urine, feces, water and a preparation made from the flies were as follows (tables 2 and 3):

Serum.—Two serum pools[6] were prepared and administered to volunteers with the following results:

Pool 1 SIH: Single specimens were collected from 8 of the "camp hepatitis patients" during the first or second week after

4. Neefe, J. R.; Stokes, J., Jr.; Reinhold, J. G., and Lukens, F. D. W.: Hepatitis Due to Injection of Homologous Blood Products in Human Volunteers, J. Clin. Investigation **23**: 836 *(Sept.)* 1944.

5. The term "inoculation" is used herein to indicate the administration of potentially infectious materials regardless of the route.

6. Pools have been designated with code letters to simplify identification. Thus the code SIH indicates serum, infectious hepatitis; NPIH, nasopharyngeal washings, infectious hepatitis; FIH, feces, infectious hepatitis; UIH, urine, infectious hepatitis.

the onset of the disease Three volunteers (group A) were injected parenterally with 1 1 cc of this pool These subjects have been observed for eleven months and no definite evidences of hepatitis have been detected

Pool 2 SIH This consisted of 39 specimens obtained from 4 volunteers before and after the onset of hepatitis produced experimentally by the oral administration of feces pool 1 FIH Three volunteers (group B) received 3 cc of this pool orally, and after twenty-six and thirty-three days respectively 2 developed infectious hepatitis with jaundice, indicating that the causative agent was present in this serum However, 3 other subjects (group C) who were injected parenterally with 2 1 cc of the same serum have shown no signs of hepatitis during the 132 days that have elapsed to date

Nasopharyngeal Washings[7]—Specimens were collected from many of the 'camp hepatitis patients" by having them gargle with sterile saline solution or beef broth Selected specimens were pooled and, without further treatment, two different pools were administered to two different groups of volunteers with the following results

Pool 1 NPIH Single specimens were collected from 6 patients during the first or second week after the initial symptoms of hepatitis Approximately 4 cc of this pool was sprayed and dropped into the nasopharynx of 3 volunteers (group D) on each of three successive days, a total volume of approximately 12 cc being administered No evidences of hepatitis have been detected during a period of eleven months

Pool 2 NPIH This consisted of single specimens collected from 20 patients during the preclinical,[8] preicteric, early, middle and late icteric stages of hepatitis Six cc was sprayed and dropped into the nasopharynx and 30 cc was administered orally to each of 5 volunteers (group E) None have shown any evidence of hepatitis during a period of seven months

Urine—One large urine pool was prepared and administered to volunteers as follows

Pool 1 UIH Single specimens collected from 38 of the "camp hepatitis patients" in the preclinical, preicteric and early, mid and late icteric stages of the disease were pooled and, without further treatment. 25 cc was administered orally to each of 7 volunteers (group F) No evidences of hepatitis have been detected in any of these men during a period of eight months

Fly Extract—In the 6th week of the camp season, during the first peak of the epidemic, a pint bottle was filled with living flies obtained from a fly trap located adjacent to the kitchen in the boys' section The flies were killed within three hours by freezing Later, after thawing, they were placed in buffered saline solution and subjected to the action of a Waring blendor The resulting preparation was then filtered twice through a Berkefeld filter, and the filtrate produced no illness in mice, rats, guinea pigs or monkeys on intraperitoneal and intracerebral injection[9]

Fifteen cc of the filtrate (fly extract) was administered orally to each of 5 volunteers (group G) No evidence of hepatitis was detected in any of these men during a period of eight months

Feces—The following preparations were administered to volunteers

Pool 1 FIH Portions of 4 specimens collected from 4 of the "camp hepatitis patients" during the 1st or 2d week after the onset of the disease were pooled and approximately a 10 per cent suspension in distilled water was prepared by mixing the feces with distilled water in a Waring blendor After being subjected to the action of the blendor for five to ten minutes, the suspension was strained through several layers of gauze and, after storage for several weeks at minus 5 to minus 20 C, was thawed and administered, without further treatment, to the volunteers

Of 16 men (groups H, I and J) receiving 1 6 to 5 cc of this pool orally, 11 developed infectious hepatitis after incubation periods of 18 19, 19, 19, 21, 22, 22, 23, 24, 24 and 26 days Ten of the 11 cases showed overt jaundice and, in these, the incubation periods did not exceed 24 days The other, who had the longest incubation period in this group, had mild but definite hepatitis without jaundice The mean incubation period for these 11 cases was 21 5 days

The men of group K each ingested a volume of water which originally had contained approximately 1 5 cc of feces pool 1 FIH Before it was administered, this contaminated water was treated with coagulants and an adsorbent (sodium carbonate, aluminum sulfate and activated carbon) in an attempt to decrease the concentration of the hepatitis agent The treatment procedure, described in detail elsewhere,[10] removed 85 per cent of the total organic solids in the specimen and made the water, formerly opalescent and pale brown, crystal clear It seems certain, therefore, that the men of group K received considerably less than 1 5 cc of feces pool 1 FIH Two of the 5 men so inoculated developed mild infectious hepatitis 1 with only scleral jaundice and the other without overt jaundice, after incubation periods of 33 and 37 days respectively

* See text † Results at time of writing (132 days), subject to change ‡ Prepared from specimens obtained from group P

7 The term nasopharyngeal washings has been used herein to indicate washings of the nasopharynx and of the oropharynx

8 The term preclinical' is used to indicate the period between infection and the first evidence, clinical or laboratory, of the disease

9 The mice rat and guinea pig tests of the fly extract and the Seitz filtrate of feces were made by Dr Werner Henle assistant professor of bacteriology in pediatrics University of Pennsylvania School of Medicine The tests of the same materials in monkeys were made by John F Enders Ph D, associate professor of bacteriology and immunology, Harvard Medical School

10 Neefe J R, Stokes J, Baty J B and Reinhell J G Disinfection of Water Containing the Causative Agent of Infectious (Epidemic) Hepatitis, this issue, p 1076

Seitz Filtrate of Pool 1 FIH: In order to determine whether the agent was filtrable, a portion of pool 1 FIH was passed through a Seitz filter. The filtrate was sterile on bacteriologic examination and produced no illness in mice, guinea pigs and monkeys. All of the 3 men (group L) receiving 2 cc. of this filtrate orally developed moderately severe to severe infectious hepatitis with jaundice after incubation periods of 28, 30 and 32 days. None of the 3 volunteers (group M) who received 1 cc. of the filtrate parenterally have developed infectious hepatitis to date (132 days).

Pool 2 FIH: This was prepared in the same manner as pool 1 FIH from portions of all specimens obtained from the men of group H during the first four weeks after the onset of hepatitis which followed their experimental inoculation with pool 1 FIH. One of the 7 volunteers (group N) who received orally 5 cc. of this pool developed hepatitis with jaundice after twenty-eight days.

Water.—On September 6, approximately two weeks after the camp had closed, specimens of water from both of the camp wells (see "Epidemiologic Observations") were collected in sterile containers, by the camp directors, for bacteriologic examination. The examination of the specimen obtained from the well in the girls' section revealed the presence of Escherichia coli, indicating fecal contamination. The specimen from the well in the boys' section was reported satisfactory for human consumption.

Collection and Storage of Water.—On October 6, 15 gallons of water was collected from the "girls' well" as follows: As water had not been pumped from this well after September 6, the water was allowed to run at full force (electric pump) for forty-five minutes from a faucet at the surface of the well. Each of three clean 5 gallon bottles then was rinsed thoroughly four times with water from the faucet, after which each bottle was filled with water, stoppered and transported to the laboratory. Circumstances did not permit a bacteriologic examination of these specimens until October 17, eleven days after collection. At that time Escherichia coli was isolated from each of the three bottles but no pathogenic intestinal bacteria were found. Owing to a lack of low temperature storage space, the water specimens were stored at room temperature in plain glass bottles, unprotected from light, in a laboratory from October 6 until November 5. On that date, thirty days after collection, approximately 12 liters of water from each of the three bottles was pooled (water specimen GW) and portions were ingested by volunteers (group P).

Criteria for Hepatic Dysfunction.—The significance of the changes that occurred in the responses of each of these men (group P) to the various liver function tests after inoculation has been evaluated by comparing them with their own preinoculation responses and also by comparing them with the results obtained in the control subjects. Such comparisons are permissible because the conditions of the experiment were uniform in respect to the inoculated and uninoculated groups and did not change throughout the period of observation. The occurrence of a single deviation from the normal in the results of one liver function test has not been regarded as significant evidence of hepatic dysfunction, because such sporadic deviations previously have been observed in supposedly normal persons or in patients with various conditions.[4] Deviations in the results of one test from the previously established normal response of that person have been regarded as evidence of hepatic dysfunction when persistent and associated with suggestive clinical manifestations or when associated with abnormal responses to one or more other tests of liver function. In order to determine the statistical significance of the changes observed in the men of group P during the postinoculation period, the normal responses of each person to the various tests, based on the studies made during the three month preinoculation period, have been calculated in terms of means and standard deviations. Values departing from the mean by more than twice the standard deviation were accepted as statistically significant deviations.

Experimental Conditions and Studies on Control Subjects.—The only variable between group P and a group of 10 control subjects confined under the same conditions in the same building throughout the period of the experiment was the ingestion of water specimen GW. The same series of liver function tests was conducted with the same frequency over the same period of time on the two groups. On the basis of these criteria, no significant indications of hepatic dysfunction were detected in the control subjects during the period of observation.

Results in Group P: On November 5, thirty days after collection, 7,000 cc. of water specimen GW was ingested by each of 5 volunteers (group P) over a period of thirty-six hours. Between the 61st and 71st days after the ingestion of this water, 4 of the 5 men developed mild illnesses characterized by nonspecific symptoms and signs associated with laboratory evidence of hepatic dysfunction. Since none of these men developed overt jaundice and because of the critical nature of this experiment, the data pertaining to the liver function tests on these men and the results of certain other related studies and experiments are presented:

(1) *Liver Function Studies.*—For convenience in description, the days after the ingestion of water specimen GW have been numbered in sequence.

W. H.: The liver function tests which showed deviations from the normal after the ingestion of water specimen GW are shown in chart 2. Sixty-five days after inoculation, the test for urine urobilinogen was positive in a urine dilution of 1 to 100 and the total serum bilirubin concentration had risen to

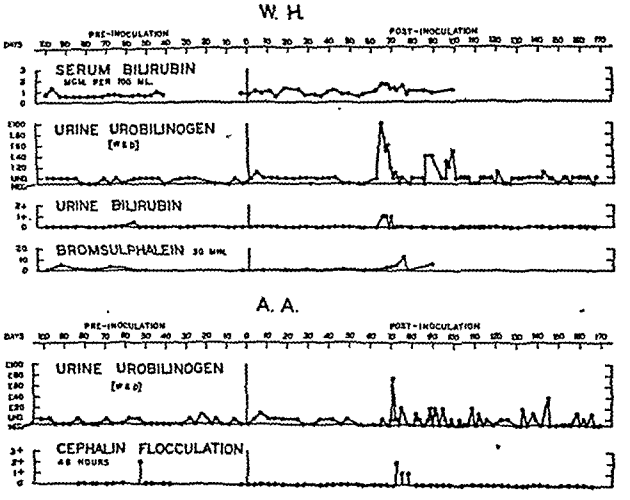

Chart 2.—Results of liver function tests in volunteers W. H. and A. A. before and after their inoculation with water specimen GW (water from well in girls' section of camp). Vertical line at 0 days indicates time of inoculation. Values for serum bilirubin indicate concentration of total serum bilirubin per hundred cubic centimeters. Urine urobilinogen readings represent highest dilution of urine with which positive reaction was obtained. Urines giving a positive reaction for urobilinogen with only the undiluted specimen are indicated at level UND on the ordinate. Urine bilirubin reactions are graded 0 to 4 plus. One plus urine bilirubin readings indicate that both the Harrison and the diazo spot tests were weakly but definitely positive. The results of sulfobromophthalein tests are expressed in percentage retention after 30 minutes. The cephalin cholesterol flocculation tests are read from 0 to 4+ depending on the degree of flocculation and clearing of the supernatant at 48 hours.

1.64 mg. per hundred cubic centimeters. The qualitative van den Bergh reaction was delayed direct and the tests for urine bilirubin were positive. The increased excretion of urine urobilinogen continued intermittently for thirty-four days, the maximum excretion being represented by a positive test with the 1:100 dilution. The total serum bilirubin concentration remained elevated for ten days, the values of the 67th, 68th and 75th days being 1.62, 1.54 and 1.44 mg. per hundred cubic centimeters respectively, all associated with delayed direct qualitative van den Bergh reactions. The tests for urine bilirubin continued to be positive until the 69th day. On the 75th day, sulfobromophthalein retention was 12 per cent at thirty minutes.

Based on the preinoculation studies, the normal response of W. H. to each of these procedures was as follows: (*a*) For 18 determinations of the total serum bilirubin concentration, the mean was 0.69 mg. per hundred cubic centimeters (S. D. ± 0.2; mean plus 2 S. D. — 1.09); (*b*) qualitative van den Bergh reaction (3 tests) negative; (*c*) the mean thirty minute sulfobromophthalein retention for 7 tests was 1.4 per cent (S. D. ± 1.9; mean plus 2 S. D. — 5.27); (*d*) urine urobilin-

(25 tests) was never positive in dilutions of 1 to 10 or greater; (*c*) urine bilirubin was absent with 23 of 24 tests; the 1 test showed an atypical color reaction and was read as suggestive (±). Compared with these, the "postinoculation" results were significantly abnormal. On the basis of the criteria cited previously, the occurrence of significantly abnormal results with 4 liver function tests during the same period has been regarded as evidence of hepatic dysfunction.

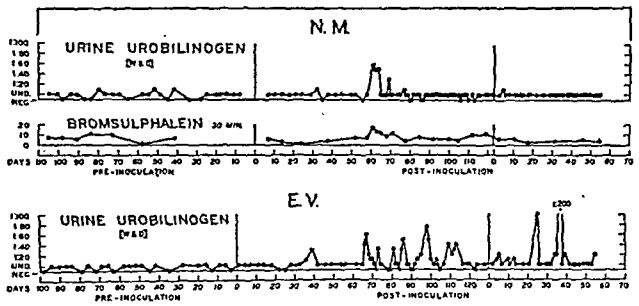

Chart 3.—Results of liver function tests in volunteers N. M. and E. V. before and after first inoculation with water specimen GW and after second inoculation with feces pool 1 FIH. Vertical line at 0 days to left of subject's initials indicates time of inoculation with water specimen GW. Vertical line at 0 days to right of subject's initials indicates time of inoculation with feces pool 1 FIH. See chart 2 for complete legend.

A. A.: The results of the tests on this subject, which were abnormal following inoculation, also are shown in chart 2. On the 71st day the test for urine urobilinogen was positive in a urine dilution of 1:75 and the test for urobilin was strongly positive. Slightly increased excretions of urine urobilinogen and urobilin continued intermittently until the 145th day. On the 72d, 75th and 78th days the cephalin cholesterol flocculation tests gave readings of 2+, 1+ and 1+ respectively.

None of the 30 preinoculation tests for urine urobilinogen were positive in dilutions greater than 1:10. Compared with preinoculation results for urine urobilinogen, the postinoculation results are significantly abnormal. Only 1 of the 13 preinoculation cephalin cholesterol flocculation tests gave a positive reaction. The degree of flocculation was read as 2+ after forty-eight hours and this was not associated with symptoms or abnormalities in any of the other tests of liver function. With the exception of this one positive test fifty-two days prior to inoculation, no flocculation had been observed with 24 subsequent tests until that observed on the 72d day. The probability is small that a positive response to the cephalin flocculation test would occur simultaneously with abnormally increased urobilinogenuria in this subject as a result of the operation of chance. The probability of this combination occurring three times in succession as the result of chance is very much smaller. The simultaneous occurrence of abnormal results with 2 different tests of liver function has been regarded, therefore, as evidence of hepatic dysfunction.

N. M.: The liver function tests showing deviations from the normal in this subject are shown in chart 3. On the 61st day the test for urine urobilinogen was positive in a dilution of 1:60 and the test for urobilin was positive. Increased excretion of urobilinogen and urobilin continued intermittently until the 69th day. Sulfobromophthalein tests on the 61st, 63d and 65th days revealed retentions of 17, 13 and 12 per cent respectively.

With the 26 tests for urine urobilinogen performed during the 105 day preinoculation period, no reaction was obtained with urine dilutions greater than 1 to 10. The mean retention for 7 sulfobromophthalein tests was 7.2 per cent (S. D. ± 3.2; mean plus 2 S. D.—13.6; range 2 to 11 per cent). Compared with these, the postinoculation results showed significant deviations from the normal. On the basis of the criteria cited, the occurrence of abnormal responses during the same period with two different liver function tests has been regarded as evidence of hepatic dysfunction.

E. V.: The only tests of liver function that showed deviations from the normal after inoculation were those for urine urobilinogen and urobilin. The results of the tests for urobilinogen in this subject are also shown in chart 3. With 25 tests during the 100 day preinoculation period, no reaction was obtained with urine dilutions of 1:10 or greater. On the 39th day post inoculation the test for urine urobilinogen was positive with a urine dilution of 1:30, and the test for urobilin was positive. No further abnormalities occurred until the 66th and 67th days, when the urobilinogen tests were positive with urine dilutions of 1:40 and 1:60 respectively. Increased excretions of urinary urobilinogen and urobilin continued intermittently for forty-seven days. The maximum urobilinogen excretion was represented by a positive test with the 1:75 dilution on the 98th day. The other liver function tests showed no significant abnormalities, but this person had somewhat more specific clinical symptoms, including an elevation of temperature ranging from 100 to 101.2 F. (rectal) on the 68th and 69th days, anorexia, nausea and two episodes of vomiting. Because of these symptoms and the occurrence of pathologic urobilinogenuria over a period of time corresponding to that in which hepatic dysfunction was present in 3 other members of the same group, the findings in this subject have been regarded as evidence of hepatic dysfunction.

(2) *Demonstration of Transmissible Agent in Feces of W. H., N. M. and E. V.*—Portions of feces specimens collected from these men (group P) during the first ten days after the onset of the illness produced by the "water agent" were pooled and a suspension in distilled water (pool 4 FIH) was prepared in the same manner as pool 1 FIH. Ten cc. of pool 4 FIH was administered orally to 5 previously uninoculated volunteers (group R). After fifty-four days 1 (J. B.) of the 5 men developed symptoms and signs similar to those which had been observed in the men of group P. The results of the tests which showed deviation from the normal are shown in chart 4. On the 54th day the test for urine urobilinogen was positive in a urine dilution of 1:40 and the test for urobilin was positive. Increased excretions of urobilinogen and urobilin in the urine occurred intermittently until the 66th day. The maximum excretion of urobilinogen was represented by a positive test with a urine dilution of 1 to 100 on the 66th day. The Harrison and diazo spot tests for bilirubin in the urine were positive on the 62d day only. A slight increase in sulfobromophthalein retention was found on the 58th and 61st days. On the 65th day he experienced a chill, and during the following twenty-four hours his temperature varied between 98 and 104 F. (rectal). Anorexia and pruritus were pronounced. The clinical symptoms and signs persisted for approximately a week with the exception of the temperature, which remained in the normal range after the 66th day. The other 4 men in group R have shown no significant symptoms or laboratory abnormalities during the period of six months which has elapsed. The incubation period and laboratory findings in the case of J. B. were similar, therefore, to those observed in the 4 men of group P following the ingestion of water specimen GW.

(3) *Electrophoretic Patterns of the Serum Proteins.*—Using the electrophoretic apparatus of Tiselius, studies were made on specimens of serum obtained at frequent intervals before and after the onset of hepatic dysfunction in N. M. and E. V. During the period of hepatic dysfunction, definite changes in the patterns of the serum proteins were found, and the sequence of changes was the same in the 2 cases. The sequence of changes also was the same as that observed in cases of hepatitis with jaundice produced by feces pool 1 FIH. The details of the protein alterations will be reported elsewhere.[11]

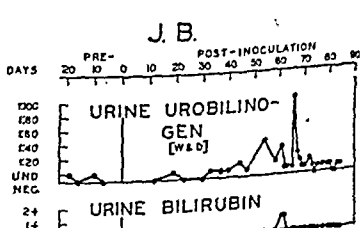

Chart 4.—Results of liver function tests on volunteer J. B. before and after inoculation with feces pool 2 FIH (specimens obtained from W. H., N. M. and E. V. during illnesses that followed ingestion of water specimen GW). See chart 2 for complete legend.

(4) *Testing of N. M., E. V., A. A. and J. B. for Immunity to Hepatitis Agent Excreted in Feces of Camp Patients.*—After complete recovery from the hepatic disturbances produced by the "water agent," these 4 men and 9 normal control subjects were inoculated with equivalent oral doses of feces pool 1-FIH. Seven of the 9 control subjects developed typical infectious hepatitis with overt jaundice after incubation periods of 19 to 26 days, whereas not one of the 4 men (N. M., E. V., A. A., J. B.) previously ill from the "water agent" has had symptoms of any illness during the 4 months elapsing to date. Subject E. V. showed an increased excretion of urobilinogen (chart 3) on the 24th and 38th days, but this was not associated with symptoms or abnormalities in the results of other liver function tests. Subjects N. M. (chart 3), A. A. and J. B. showed no deviations from the normal in the results of any of the liver function tests. The failure of any of these 4 men to develop definite evidence of hepatitis represents a statistically significant difference (chi square 4.01) from the results obtained in the 9 normal controls. This difference provides significant evidence that N. M., E. V., A. A. and J. B. were immune to the hepatitis agent responsible for the camp epidemic.

C. THE TRANSMISSION EXPERIMENTS

The results of the transmission experiments provide considerable information concerning the source of the camp agent and its possible methods of transmission.

The nasopharyngeal washing and urine pools contained specimens from 26 and 38 infected persons respectively. Specimens obtained both before and after the onset of hepatitis were included. If the causative agent were commonly present in the nasopharynx or urine, it should have been present in these pools. The experience with other materials make improbable the possibility that the agent, if present, was destroyed by the procedure of collection or during the period of storage. Relatively large doses were used because of the possibility that the concentration of the agent, if present, was low. That the volunteers included susceptibles is indicated by the fact that five months after inoculation with pool 2 NPIH 1 of the men was inoculated with feces pool 1 FIH and developed hepatitis with jaundice after 22 days. The evidence indicates, therefore, that the causative agent probably was not present in the nasopharyngeal washings and urine of 26 and 38 patients respectively. This, in turn, suggests that the main source of the agent at the camp was not the nasopharynx or the urine of the infected persons.

The oral transmission experiments showed that the agent was present in serum. However, parenteral injection of serum (and the Seitz filtrate of feces) known to contain the agent has not produced the disease in the 132 days that have elapsed at the time of writing. Parenterally injected blood or serum, therefore, hardly could be responsible for the large number of early cases appearing at the camp within 42 days after arrival. Since the members of the camp group could not have received blood or serum orally, the results of these experiments indicate that the majority of the camp cases were not infected after arrival by serum or blood.

The oral transmission experiments showed that a hepatitis agent was excreted in the feces of infected persons. The results in groups H and N, representing two human passages of this agent in feces, clearly show that the agent was transmissible, and the results in group L show that it passed through a Seitz filter. Furthermore, the oral administration of these materials consistently produced the disease after incubation periods of 19 to 37 days, indicating that direct or indirect transmission of the agent from feces could have been responsible for the camp epidemic.

The results in groups H, I and J compared with those in groups K and L suggest that the length of the incubation period may be influenced by the amount of the agent administered orally. Although methods of measuring the concentration of hepatitis agent in a given material have not been developed, it is known that Seitz filtrates of materials containing other viruses have a lower concentration of those viruses than the unfiltered materials.[12] It is probable, therefore, that the 2 cc. dosage of the Seitz filtrate of pool 1 FIH (group L) contained a smaller amount of the hepatitis agent than the quantities of the unfiltered material given to groups H, I and J. It also seems reasonably certain that the men of group K received a smaller amount of the hepatitis agent than did the men in groups H, I and J. The mean incubation period for the combined groups H, I and J (11 cases) was 21.5 days and the longest incubation period was 26 days. For the combined groups K and L (5 cases) the mean incubation period was 32 days and the shortest incubation period was 28 days. The absence of any significant differences in the severity of the illnesses of the men in groups H, I and J as compared with those of the men in group L affords some evidence that the longer incubation periods in the men of group L probably were due to smaller doses of the agent rather than to a change in its virulence resulting from the filtration process. However, the illnesses in the men of group K were much milder than those of the men in groups H, I, J and L, suggesting that the virulence, as well as the concentration, of the agent received by group K may have been decreased by the treatment to which it was subjected. Although these groups are too small for the results to be conclusive, the available evidence suggests that the length of the incubation period may be related inversely to the quantity of ingested hepatitis agent and possibly to its virulence.

As previously stated, the water from the girls' well showed bacteriologic evidence of fecal contamination. Since the hepatitis agent was excreted in feces, the contamination of this water with feces strongly suggests that water may have been the means of transmission of the agent at the camp. However, the occurrence, after the usual incubation period, of hepatitis in human volunteers following the ingestion of this water under controlled conditions would constitute the only conclusive proof that the water contained the hepatitis agent. For this reason the conclusions regarding the method of transmission of the agent at the camp depend to a considerable extent on the interpretation of the results obtained by the administration of water specimen GW to volunteers (group P). The occurrence of illnesses associated with hepatic dysfunction in 4 of the 5 men at nearly the same time after ingestion of this water and the absence of any similar disturbance among control subjects living under the same conditions definitely relate the illnesses in these men to the one variable, namely the ingestion of water specimen GW. The individual liver function tests giving abnormal results in this group of men during their illnesses included those for urine urobilinogen, urine urobilin, urine bilirubin, serum bilirubin, qualitative

12. Henle, W.: Personal communication to the authors.

van den Bergh reaction, cephalin cholesterol flocculation and sulfobromophthalein excretion. Abnormal results with this group of tests can be regarded as unquestionable evidence of hepatic dysfunction, regardless of the cause. The demonstration of the presence of an agent capable of producing the same illness when administered to other volunteers (group R) in the feces of these men indicated that the illnesses were due to a transmissible agent. Since the chances of isolating two different transmissible agents that produced hepatic dysfunction, one from the feces of the camp patients and the other from the camp water supply, would be extremely small, it is logical to assume that the "water agents" and the "feces agent" were the same. This assumption is supported by: (*a*) The electrophoretic studies, which showed that the illness produced by the "water agent" and the hepatitis produced by the "feces agent" were associated with the same sequence of changes in the serum proteins.[13] The significance of the sequence of changes occurring in the serum proteins during hepatitis has not yet been established. However, in 5 cases (with jaundice) studied to date the sequence

TABLE 4.—*Incubation Periods in Persons with Limited Periods of Exposure*

	Exposure				Incubation Period	
Case	Date or Dates	Duration	Place	Date of Onset	Minimum	Maximum
A	7/27/44	2 hours	Camp	9/ 2/44	37	37
B	7/27/44	12 hours	Camp	8/12/44	34	34
C	7/29/44	12 hours ±	Camp	8/28/44	30	30
D	8/3 to 8/8/44	5 days	Camp	9/ 2/44	25	30
E	7/9 to 7/19/44	8 days	Camp	8/12/44	26	34
2	6/30 to 7/7/44	8 days	Camp	7/24/44	20	28
F	8/25 to 9/2/44	8 days	Philadelphia	10/ 3/44	31	39
G	8/7 to 8/13/44	7 days	Hospital	8/21/44	8	14

of changes has been the same and thus appears to be a characteristic occurrence in hepatitis. Whether the same sequence of changes occurs in other diseases is not known, so that these findings cannot be regarded as characteristic only of hepatitis. (*b*) The experimental evidence showing that N. M., E. V., A. A. and J. B., after recovery from the hepatic disturbances produced by the "water agent," were immune to the "feces agent."

However, the illness produced in the men of groups P and R by the "water agent" differed from that produced by the agent in the feces of the camp patients in the following two ways: (*a*) None of the 5 men developed overt jaundice; (*b*) the incubation periods ranged from 54 to 71 days. The fact that hepatitis may occur without jaundice is now well established. The ratio of cases with jaundice to those without jaundice apparently varies in different epidemics from approximately 2.7 to 1 as observed in this epidemic to estimates of 1 to 2 or more in Italy.[17] Thus the failure of the men in groups P and R to develop overt jaundice does not constitute evidence that they did not have hepatitis. However, if the "water agent" was the same as the "feces agent," at least 1 of the 5 men might have been expected to develop overt icterus unless a decrease in virulence of the agent had occurred. At the time of collection of water specimen GW, no water had been pumped from the well for at least 5 weeks and the camp had been closed for 8½ weeks. The water specimen then was stored in a laboratory at room temperature in plain glass water bottles, unprotected from light, for another month before it was administered to group P. These conditions could have resulted in attenuation of the hepatitis agent. In addition, it is reasonable to assume that the concentration of the agent in this water probably was low, and the results of the transmission experiments in groups H, I and J, and in groups K and L have indicated that the length of the incubation period may vary inversely with the amount of the agent ingested. Additional evidence that the quantity of virus administered to human beings may influence the length of the incubation period is provided by the recent report of the Commission on Acute Respiratory Diseases.[18] The investigators found that the incubation period of primary atypical pneumonia produced experimentally in volunteers by the administration of a filtered material was approximately one week longer than that following the administration of the same amount of this material prior to the filtration. The longer incubation periods and the mildness of the disease observed in groups P and R could be explained, therefore, by a low concentration of attenuated virus.

D. CONCLUSIONS BASED ON TRANSMISSION EXPERIMENTS

1. The main source of the hepatitis agent at the camp probably was the feces of infected persons.

2. The agent in feces was transmissible to human beings.

3. The agent in feces passed through a Seitz filter.

4. The evidence indicates that water from the girls' well contained a hepatitis agent which probably was the same as that excreted in the feces of the camp patients.

5. The agent probably was present in the blood of infected persons at some stage of the disease.

6. Nasopharyngeal droplets or secretions and urine probably were not common sources of the agent at the camp.

III. EPIDEMIOLOGIC OBSERVATIONS

In this report, only the factors related to the sources of the agent and its method or methods of transmission at the camp will be considered.

A. INCUBATION PERIOD

The most satisfactory data on the length of the incubation period are those pertaining to a few persons who had a more limited period of exposure than the members of the camp group (table 4). In 3 persons who visited the camp for only 2 to 12 hours on 1 day (patients A, B and C) the incubation periods were 30, 34 and 37 days. In 2 who visited for 5 and 8 days (patients D and E), the minimum periods were 25 and 26 days and the maximum were 30 and 34 days respectively. The female counselor (patient 2) who was exposed to the initial case for the first 7 days

13. The changes in the various protein components demonstrated by the electrophoretic method were not shown by quantitative chemical determinations on the same specimens.

developed the disease after a minimum period of 20 and a maximum period of 28 days. After a boy camper had returned to his home, his cousin (patient F) visited him in his home for a week and left the day before he developed the initial symptoms of hepatitis. Case F developed the disease after a minimum period of 31 and a maximum incubation period of 39 days. The shortest incubation period apparently was that of a hospital nurse (patient G) who was never at camp but who constantly attended a boy camper for 7 days during the preicteric period of his illness. Her first symptoms occurred after a minimum period of 8 and a maximum period of 14 days. However, overt jaundice did not appear for 24 days after her first symptoms. Finally, 53 persons (chart 1) developed the disease during the 6th week of the camp season. Since it is unlikely that these persons were all infected immediately on arrival, the incubation periods were probably less than 42 days. Thus the possible range of the incubation periods in these 61 cases of hepatitis was 8 to 42 days, and in 3 of those in which exposure was limited to 1 day it was 30 to 37 days.

The incubation periods observed in volunteers experimentally infected with feces pool 1 FIH (specimens obtained from camp group) ranged from 19 to 37 days, thereby substantiating the foregoing observations.

These data on incubation periods, those reported by others [19] and the evidence of infection of visitors to the camp provide support for the basic assumption necessary for a discussion of the method or methods of transmission, namely that the majority of the camp group acquired the infection after arrival at camp. This assumption is supported by the fact that many of those involved early were from different cities and towns. Their nearly simultaneous infection with a hepatitis agent by natural means before coming to the camp would therefore be almost impossible. The data on incubation periods also indicate that patient 1, who developed hepatitis only 3 days after arrival, was infected elsewhere.

B. SOURCE OF HEPATITIS AGENT

Since hepatitis had not occurred at this camp in previous years and no other source of the agent has been detected, it is reasonable to assume that it originated from patient 1, who developed the disease 3 days after the opening of the camp. This is supported by the following facts: (1) the second person (patient 2) to develop the disease lived in the same cabin (A) and was therefore closely exposed to case 1 before and after the onset of hepatitis; (2) in relation to the time of onset in case 1, the epidemic began after an interval of time that is compatible with the observed length of the incubation period of the disease.

The source of the infection of patient 1 is unknown. She had had no recognized exposure to patients with hepatitis and no injection of a homologous blood product.

C. CHARACTERISTICS OF THE EPIDEMIC

As shown in chart 1, the early cases occurred predominantly in the female group. The first 2 persons (patients 1 and 2) to develop the disease lived in the same cabin (A). The onset in case 1 was on the 3d day of the season and in case 2 the disease developed 24 days later but approximately 10 days before the explosive appearance of the epidemic. This suggests that patient 2 was infected earlier and possibly by a different method than the others. However, the 40 persons in the female group who developed signs of the disease during the 6th week were quartered in a number of different cabins and had no unusual exposure to the earlier cases. In fact, as patient 1 was confined to cabin A from the 4th to the 6th day and to the girls' infirmary from the 7th to the 10th day and left for her home on the 11th day, the period during which the female group as a whole could have been exposed to her was limited to the first 3 days. Furthermore, the 13 persons in the male group who developed hepatitis during the 6th week also lived in different cabins and included young campers who would have had little or no chance of being exposed to the early cases in the female group. Thus, a relatively large number of the female group and a small number of the male group apparently were infected at nearly the same time by some method that did not require personal contact. Furthermore, the low incidence of secondary cases previously mentioned indicates that the agent was not easily transmitted to contacts. The data on the incubation period of the disease show that it did not exceed 42 days in the 61 cases on which satisfactory data are available. Thus, the fact that the disease continued to appear in members of the camp group over a period of at least 70 days suggests that, although a number of persons in both the male and female groups were probably infected at nearly the same time, others were probably infected at different times. This is indicated also by the facts that the majority of the cases in the female group occurred earlier than the majority in the male group and the incidence curves in both groups showed two distinct peaks (chart 1). For these reasons a source of infection must have been present over a period of time. The occurrence of hepatitis in persons who arrived at or visited camp during the 2d, 4th, 5th and 6th weeks indicates that a source of infection was present for at least the first 6 weeks.

Thus, the chief epidemiologic characteristics requiring explanation are (1) the unusually high incidence of the disease in the entire camp group, which appears to be the highest that has been reported in any group in this country during a similar period of time; (2) the higher total incidence in the female than in the male group; (3) the predominance of the early cases in the female group and the later cases in the male group; (4) the simultaneous infection of a number of persons at the camp who had not been in close personal contact; (5) the infection of others after a longer period of residence at the camp; (6) the apparent ease with which the infectious agent was acquired at the camp in contrast to the apparent lack of ease with which it was acquired by those in contact with infected persons away from the camp.

D. POSSIBLE METHODS OF TRANSMISSION OF THE CAUSATIVE AGENT

In order to obtain a satisfactory explanation for the described characteristics of the epidemic, the various methods by which the infectious agent might have been transmitted at the camp have been investigated. The evidence for and against these methods, as provided

[19] Epidemic Infective Hepatitis, editorial, Brit. M. J. 2:680 (Nov. 27) 1943. Ford, J. C.: Infective Hepatitis, Lancet 1:675 (May 29) 1943.

by the observations made at the camp and by the results of the transmission experiments in volunteers, is as follows:

Transmission by Air.—The members of the camp group lived in cabins accommodating 7 to 10 campers and 1 to 2 counselors. Circulation of air in and out of cabins was free. Beds were approximately 3 feet apart. The entire male and female groups ate at one time in their respective dining rooms, each of which consisted of a single large airy room with many small tables accommodating 10 to 12 persons. Thus there was ample opportunity for transmission of an infectious agent by air. However, the explosive type of the onset of the epidemic, the infection soon after arrival at camp of some persons in the male group who had not been in close personal contact with the female group, the lack of ease with which the agent was acquired away from the camp and the failure of nasopharyngeal washings to produce the disease in volunteers all indicate that the majority of persons were not infected by an air borne agent.

Transmission by Fomites.—Because of the well known tendency of young persons to use articles in common, spread of the infectious agent by this means would have been quite possible in groups such as these. Undoubtedly certain articles in the cabins were used by several or all of the residents. Dishes and eating utensils were washed by hand, rinsed in hot water and then in a germicidal solution (Roccol-Winthrop Chemical Company). However, the care with which this procedure was carried out was subject to individual variation and, in view of the known resistance of the hepatitis agent to some methods which destroy bacteria, the agent might have survived the cleansing process. For these reasons, transmission by fomites may have been the method responsible for the infection of some persons at the camp and also for the 5 persons who had not been at the camp. However, the same observations cited under transmission by air indicate that fomites probably were not responsible for transmitting the agent to the majority of the persons at the camp.

Transmission by Biting Insects.—Since extremely small amounts of serum injected parenterally have transmitted a hepatitis agent to volunteers [20] and evidence has been obtained that suggests transmission by the minute amounts of serum remaining in improperly sterilized syringes and needles,[21] it might be possible for biting insects to transmit mechanically the agent in blood from one person to another. Since "stable flies," "deer flies" and mosquitoes were unusually abundant at the camp from the beginning of the season, there would have been ample opportunity for this type of transmission. However, parenteral injection of a pooled serum and a Seitz filtrate of feces (both known to contain the camp hepatitis agent) into previously uninoculated volunteers (groups C and M) has not resulted in hepatitis in the 132 days that have elapsed to date. This provides reasonable evidence that the many persons developing hepatitis within 40 days after arrival at the camp were not infected from blood carried by biting insects. This method, therefore, probably was not responsible for transmitting the agent to the majority of the cases, although it cannot be eliminated as a possible means of infection of some persons who developed the disease in the later weeks of the epidemic. One other observation also suggests that the agent was not transmitted by biting insects. A number of persons spent varying amounts of time during the camp season at a small boarding house located adjacent to the camp. The distance between this boarding house and the girls' section was no greater than that between the midpoints of the boys' and girls' sections. The source of water for the boarding house was different from that of the camp. Questionnaires were sent to 42 persons who had not visited at the camp but had resided at the boarding house during the camp season. None had subsequently developed hepatitis. If the agent had been transmitted by biting insects, it would seem that some of these persons also would have been infected.

Direct Transmission from Person to Person.—Ample opportunities for this method of spread obviously would be present in groups such as those at the camp. Although some persons may have been infected in this way, direct transmission would not account for the explosive type of onset of the epidemic, involving persons, in both the female and male groups, who apparently had not been in close personal contact with other infected persons. It is unlikely, therefore, that direct transmission of the infectious agent from person to person was responsible for the majority of the camp cases.

The evidence cited has indicated that in the majority of the early cases at the camp infection probably did not occur by an agent transmitted directly from person to person, or indirectly by air, fomites or biting insects. The explosive type of onset of the epidemic suggests that a large number of persons were infected at approximately the same time. This indicates that the infectious agent was acquired from a common source to which a large number of persons were exposed at nearly the same time. In epidemics of other diseases which have been characterized by an explosive onset a common source of infection usually has been found, and the source usually has been contaminated food, milk, water or other materials which had been ingested by, or injected into, a number of persons within a short period of time. Since the members of the camp group had not been injected with any material before or after arrival, food, milk or water remained as possible sources of infection.

Transmission by Food.—The camp food supplies were procured from outside sources and were delivered to the boys' camp. The food supplies for the girls' section were obtained from the storeroom in the boys' section and all food, with the exception of pastries and desserts, was prepared and cooked by different personnel in the respective kitchens of the two sections. Pastries and desserts were prepared in the "boys' kitchen" and sent to the girls' section. Thus food was sent from the boys' to the girls' section, but no food was transferred from the girls' to the boys' section. Since the epidemic originated in the girls' section and no food was sent from there to the boys' section, the early cases in the boys' section could not have been caused by a food borne agent. It is also improbable that infection in the early cases in the female group were caused by a food borne agent for the following reasons: (*a*) none of the early cases in the girls' section had had any contact with food supplies, and eating utensils contaminated by those involved were not a probable means of infection of the majority of cases for reasons previously discussed; (*b*) none of the food handlers were among the early cases of hepatitis and none had had the disease previously, at least not in a recognizable form; (*c*) none of the cooks, all of whom were in the older age group, developed the disease before or after the onset of the epidemic; (*d*) the persons involved in the explosive onset of the epidemic, although predominantly females, also included a number of the male group; (*e*) contamination of food in both sections with an infectious agent carried by insects was not likely because insects had little or no access to feces which the transmission experiments have indicated was the probable source of the infectious agent; (*f*) several persons who visited the camp for only a few hours on one or more days, but did not eat there, subsequently developed hepatitis. These observations indicate that food probably was not the carrier responsible for transmission of the agent to the persons involved in the early phases of the epidemic.

Transmission by Milk.—All milk was obtained from the same dairy and was delivered to the kitchens of both sections of the camp. If the milk had been contaminated prior to arrival at the camp, the outbreak of the disease should have occurred simultaneously in the two sections. Also other camps in the

20. Oliphant, J. W.; Gilliam, A. G., and Larson, C. L.: Jaundice Following Administration of Human Serum, Pub. Health Rep. **58**: 1233 (Aug. 13) 1943. Oliphant, J. W.: Jaundice Following Administration of Human Serum (Harvey Lecture), Bull. New York Acad. Med. **20**: 429 (Aug.) 1944.

21. Salaman, M. H.; King, A. J.; Williams, D. I., and Nicol, C. S.: Prevention of Jaundice Resulting from Antisyphilitic Treatment, Lancet **2**: 7 (July 1) 1944. Sheehan, H. L.: Epidemiology of Infective Hepatitis, ibid. **2**: 8 (July 1) 1944.

vicinity, using the milk from the same dairy, had no cases of hepatitis. These observations justify the exclusion of milk, contaminated prior to arrival at the camp, as a source of the infectious agent. That milk contaminated after arrival at the camp probably was not the source of infection in the early cases is indicated by the observations relating to food as described.

Transmission by Lake Water.—During the camp season, nearly every one bathed in the camp lake at one time or another. This lake was used only by the camp group and was fed by streams which were not subject to any known source of contamination. Since many persons bathed in this lake prior to the onset of the epidemic, it is possible that the water might have been contaminated with the hepatitis agent from them, resulting in the infection of some persons. However, patient 1 did not bathe in the lake because of the onset of her illness 3 days after arrival. Furthermore, a few persons who did not bathe in the lake developed the disease in the early phases of the epidemic. Finally, several persons who visited the camp for only a few hours on one day and did not go into the lake subsequently developed hepatitis. Thus, it is not likely that, in the early cases at least, the infection was acquired from the lake water.

Since food, milk and the lake water apparently would not account for some of the main features of the epidemic, drinking water alone remained a possible source of the infection.

Transmission by Drinking Water.—The water used for drinking and washing purposes at the camp all came from two driven wells, one (approximately 220 feet deep) located in the girls' section and the other (approximately 190 feet deep) located in the boys' section. The girls' section was supplied entirely by water pumped directly from their well into the lines or from their reservoir located adjacent to the well. However, the supply from the boys' well was often inadequate and therefore was supplemented frequently by water pumped directly from the girls' well to a reservoir located in the boys' section. Thus the water used by the female group came only from their well, whereas that used by the male group came from both wells. Water from the girls' well first was pumped into the boys' reservoir during the first week of the season and thereafter was pumped into this reservoir at frequent intervals until the camp was closed. Thus contamination of the water from the boys' well with the hepatitis agent would not account for the epidemiologic phenomena. However, contamination of the water in the girls' well would satisfactorily explain (*a*) the higher total incidence in the female than in the male group; (*b*) the predominance of the early cases in the female group and the later cases in the male group; (*c*) the infection of a number of persons in both groups soon after their arrival at camp; (*d*) the persistence of a source of infection during at least the first 6 weeks; (*e*) the apparent ease with which the agent was acquired at the camp in contrast to the apparent lack of ease with which it was acquired away from the camp; (*f*) the unusually high incidence of the disease in the entire group within a period of 7 weeks.

In addition, continuous, and possibly increasing, contamination of the water in the girls' well with the hepatitis agent would provide an explanation for the two peaks in the weekly incidence curves of both groups (chart 1). Sufficient amounts of agent could have been provided by the feces of patients 1 and 2 to account for the early infection of a considerable number of persons in the female section where the well water was not "diluted" with water from other sources. In the male section, most of the water was provided by their own well, the proportion contributed by the girls' well being relatively small. This would explain the occurrence of only a few cases in the boys' section during the week in which the highest incidence was observed in the girls' section. Continued contamination of the boys' water with that from the girls' well would result in the eventual infection of a sufficient number of persons to explain the first peak in the male epidemic curve. The delayed secondary peaks in both groups would be best explained, however, by not only continuous, but also increasing, contamination of the water. An increased contamination would have been most apt to occur when the early cases in the female section were admitted to the infirmary (see Sources of Contamination of Girls' Well Water). This explanation is supported by the fact that the two peaks in the incidence curves of both groups were separated by an interval of 4 weeks, which is equivalent to the length of the incubation period. The lower height of the secondary peak in the female group as compared with that in the male group might be explained by the facts that (*a*) the chance of acquiring the agent early was greater in the female section and the number of female susceptibles, therefore, was reduced more rapidly, (*b*) the length of the period during which the agent might have been acquired was shorter as a result of the earlier closure of this section, and (*c*) the total number of persons in the group was smaller. Although the secondary peaks can be explained satisfactorily on the basis of continued, and possibly increasing, contamination of the water, the large number of early cases also provided increasing opportunities for acquiring the agent from sources other than water. The interval between the primary and secondary peaks also supports this possibility. On the other hand, the apparent lack of easy transmissibility of the agent, as observed away from the camp, suggests that the sources other than water probably were not, by themselves, responsible for the secondary peaks. It is quite possible, however, that these sources contributed to the height of these peaks.

From the evidence cited to date, transmission by water from the girls' well appears to be the only method which, on theoretical grounds alone, could satisfactorily explain the chief characteristics of this epidemic. The theoretical explanation has been substantiated by the following facts: (*a*) The transmission experiments showed that the causative agent was excreted in feces; (*b*) the water from the girls' well showed bacteriologic evidence of fecal contamination on two different occasions; (*c*) the transmission experiments provided evidence that water from this well contained a transmissible agent that produced in volunteers an illness associated with hepatic dysfunction and an immunity to the agent excreted in the feces of the camp patients. The combined results of the epidemiologic and bacteriologic studies and the transmission experiments in volunteers have led to the conclusion that the infectious agent was transmitted to the majority of the camp cases by water from the girls' well.

Possible Sources of Contamination of Water from Girls' Well.—On the basis of the foregoing conclusion, attempts were made to locate a source of contamination of the water from the girls' well. The toilets were of a type that would not permit "back flow" of fecal material into the water lines. The water reservoir was covered and was not subject to contamination except from the entering water. The well was covered at its surface, and contamination could not have entered from above. A search for leaks in the pipe lines revealed none. For these reasons the contaminating material probably entered the well below its surface. The only apparent sources of contaminating material were a number of cesspools located within a radius of 200 feet from the well. These cesspools were 6 to 8 feet in depth and had open bottoms, stone walls and cement tops. Each cesspool received the sewage and waste water from one to three cabins. None of the cesspools had overflowed prior to the start of the epidemic. In fact, although in use for a number of years, drainage of the cesspools had never been necessary, indicating that the contents had diffused into the ground. The ground layer of the area, varying in depth from a few inches to approximately 4 or 6 feet, consisted of ordinary top soil overlying a layer of "hardpan." The exact nature of the underlying rock was not determined, but it was said to consist of red shale and limestone. In certain places where the rock layer protruded through the soil and could be inspected, many cracks and fissures were apparent.

As shown in chart 5, the girls' well was nearly surrounded by cesspools. The sewage from cabins C and D was received by cesspools 3 and 4, located 200 and 100 feet respectively from the well. None of the persons living in these cabins were among the earliest to acquire hepatitis. However, cesspool 1,

located 150 feet from the well, received all the sewage from cabin A and the girls' infirmary. As mentioned previously, patient 1, who developed hepatitis 3 days after the opening of the camp, and patient 2, who developed hepatitis 27 days after the opening of the camp and approximately 1 week before the onset of the epidemic, both lived in cabin A. Furthermore, most of the early cases of hepatitis were "hospitalized" in the girls' infirmary. Thus cesspool 1 probably received feces containing the hepatitis agent almost continuously after the opening day of camp. Since the girls' well water must have been contaminated with the hepatitis agent soon after the opening of the camp to result in the explosive onset of the epidemic during the 6th week, and cesspool 1 was the only one relatively certain to have contained the hepatitis agent during the first few weeks, it is highly probable that cesspool 1 was the source of contamination. Another possible source of the hepatitis agent after the 6th week would have been cesspool 2, located only 75 feet from the well. This pool received sewage from the girls' lodge. Prior to the epidemic, the lodge was used only on the infrequent rainy days. In the 6th and 7th weeks, however, the number of cases of hepatitis exceeded the capacity of the girls' infirmary, and during that period approximately 45 hepatitis patients were quartered in the lodge. Thus during and after the 6th week either or both cesspool 1 and 2 could have provided increasing amounts of the hepatitis agent.

Unfortunately the probable relationship between the epidemic and cesspool 1 (and possibly cesspool 2) did not become apparent until the analysis of the epidemiologic data had been completed (November 1944). By that time the contamination of the well water had ceased,[22] possibly because of the lack of use of the cesspools after August 20. Thus the opportunity of obtaining additional evidence of a connection between the well and the cesspools was missed.

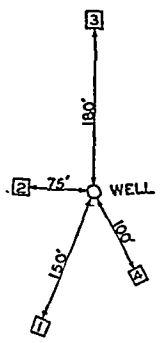

Chart 5. — Approximate location of cesspools in relation to well in girls' section of camp. Well is indicated by circle at point of convergence of arrows. Cesspools are indicated by numbered squares. Numbers on arrows represent approximate distance in feet from cesspools to well. Cesspool 1 received the sewage from cabin A and the female infirmary. Cesspools 2, 3 and 4 received the sewage from cabin B, the female lodge and cabin C respectively (see text).

The epidemiologic observations and the results of the experimental studies have led to the following conception of the pathogenesis of this epidemic: The hepatitis agent was brought into the camp on the first day of the season by patient 1. By means of a connection between cesspool 1 and the well in the girls' section, the water supply was contaminated with this agent. The majority of persons in both groups and some visitors probably acquired the agent from the water. Some persons may have acquired the agent (*a*) from feces, directly or indirectly; (*b*) possibly from blood carried by biting insects.

IV. COMMENT

On the basis of the epidemiologic observations alone, water from the girls' well appeared to be the only means of transmission of the hepatitis agent at the camp which could satisfactorily account for the chief characteristics of this epidemic. The transmission experments showed that the hepatitis agent was excreted in feces, and the bacteriologic studies provided evidence of fecal contamination of the girls' well water. Finally, the transmission experiments provided experimental evidence that this water contained a transmissible agent which probably was the same as that excreted in the feces of the camp patients. It is possible that the agent was transmitted to some persons at the camp (*a*) directly from infected persons, (*b*) indirectly by contaminated fomites or lake water and (*c*) in blood carried by biting insects. However, the data provided by the epidemiologic observations, the bacteriologic studies and the transmission experiments in volunteers all lead to the conclusion that the hepatitis agent was transmitted to the majority of the camp cases by water from the girls' well.

The evidence presented herein of the excretion of the hepatitis agent in the feces of patients with the disease confirms that previously reported by others.[23] It seems certain, therefore, that feces is the source of the agent responsible for many epidemics of infectious hepatitis and that anything subject to contamination with feces is a potential means of transmission of this disease.

The results of this investigation suggest that the agents responsible for some of the past epidemics of infectious hepatitis may have been water borne. Fraser[24] and Hallgren[25] have reported epidemics of infectious hepatitis in which transmission by water was suspected because of bacteriologic evidence of fecal contamination. However, the epidemic reported herein appears to be the first epidemic of infectious hepatitis in which experimental evidence of the method of transmission has been obtained.

It is apparent that the prevention of future epidemics of hepatitis may depend in part on the control of the agent (or agents) in water. In view of the known resistance of this agent to procedures which usually eliminate or destroy bacteria,[26] the effect of the current methods of water disinfection on this agent becomes a question of importance. Evidence recently has been obtained that the agent of infectious (epidemic) hepatitis in contaminated water was not inactivated by treatment of the water with sufficient chlorine to provide a residual concentration of 1 part per million after 30 minutes' contact. It also may have survived, in a much attenuated form, the treatment of contaminated water with sufficient chlorine to provide a residual concentration of 15 parts per million after 30 minutes' contact.[10] It is probable, therefore, that special measures, yet to be determined, will be required to eliminate the hazard of transmission of this agent by water.

The outbreak of "gastrointestinal upsets" that occurred in the camp group 1 to 3 weeks prior to the onset of the epidemic of acute hepatitis is of interest. It is possible that these manifestations were entirely unrelated to the epidemic disease. However, it seems probable that some relationship existed. If so, they may have been due to an agent, other than the hepatitis agent, that also was present in the water as a result of fecal contamination. On the other hand, it is possible that these symptoms and signs represented the first manifestations of the hepatitis agent. A number of the group who developed hepatitis 3 to 4 weeks after returning home reported similar transient upsets 1 to 3 weeks prior to the abrupt onset of acute hepatitis. Furthermore, 3 of the volunteers inoculated with feces pool 1 FIH had similar transient episodes 1 to 2 weeks before the onset of acute hepatitis. One of the 3 had

22. Bacteriologic examination of water obtained from the girls' well on Nov. 28, 1944 and of 3 specimens obtained during March and April 1945 showed no evidence of contamination.

bilirubinuria for 2 days during that period. In a previous report, evidences of the occurrence of transient symptoms and signs associated with mild hepatic dysfunction 1 to 3 months prior to the onset of acute homologous serum hepatitis has been presented.[4] These observations suggest that the "gastrointestinal upsets" observed at the camp prior to the epidemic of hepatitis may have been the first manifestations of the disease.

V. SUMMARY

During the late summer of 1944 an epidemic of infectious hepatitis occurred in a large summer camp for boys and girls. Three hundred and fifty of 572 persons developed hepatitis within a period of 13 weeks. The onset of the disease in 344 of the 350 patients was within a period of 7 weeks. This appears to be the highest recorded incidence of this disease in any group in this country over a similar period of time. Of the 350 patients with hepatitis 255 had overt jaundice and the remaining 95 had the nonicteric form of the disease. At least 9 persons who visited the camp for short periods during the first 6 weeks of the season subsequently developed hepatitis. Approximately 175 persons returned to their homes after the onset of hepatitis at the camp, and approximately 175 others developed the disease as late as 5 weeks after their return home. Among the many friends and relatives who had not visited the camp but subsequently were exposed at home to infected persons from the camp, only 5 secondary cases have been reported. No deaths occurred.

The outstanding characteristics of the epidemic were (1) the unusually high incidence of the disease, (2) the higher total incidence in the female than in the male group, (3) the predominance of the the early cases in the female group and of the later cases in the male group, (4) the simultaneous infection of a number of persons at the camp who had not been in personal contact with one another and (5) the apparent ease with which the infectious agent was acquired at the camp in contrast to the apparent lack of ease with which it was acquired by those in contact with infected persons away from the camp.

In order to determine the source of the causative agent and the method or methods of transmission at the camp, an epidemiologic survey was made and human volunteers were inoculated with serum, nasopharyngeal washings, urine and feces collected from the camp patients, and with water, and a preparation made from flies, obtained at the camp.

The transmission experiments in volunteers provided the following information concerning the source of the agent and its methods of transmission: (1) Nasopharyngeal droplets or secretions and urine probably were not common sources of the agent because of the failure of these materials to produce the disease in volunteers; (2) the agent was present in the blood and feces of infected persons; the agent in these materials produced the disease in volunteers, indicating that it was transmissible; (3) serum produced the disease in human volunteers after an incubation period similar to that observed at the camp only when given by the oral route; normal volunteers injected parenterally with the same serum have not developed hepatitis during the 132 days which have elapsed to date; (4) the chief source of the agent at the camp probably was the feces of infected persons; (5) a preparation made from flies trapped at the camp did not produce the disease in volunteers, suggesting that these flies were not carrying the caustive agent; (6) the production of the disease in volunteers by a filtrate obtained by the passage of feces through a Seitz filter indicated that the agent was filtrable; (7) a decrease in the quantity of the agent administered orally apparently resulted in an increase in the length of the incubation period; (8) water from one of the camp wells (female section) produced in 4 of 5 volunteers a mild illness associated with hepatic dysfunction. These illnesses and hepatitis produced in other volunteers by the "feces agent" were associated with the same sequence of changes in the electrophoretic patterns of the serum proteins. A second human passage of the "water agent" was accomplished by the administration to other volunteers of feces obtained from the men infected with the "water agent." After recovery from their infection with the "water agent" the 4 men tested showed evidence of immunity to the "feces agent."

The epidemiologic observations and the results of the transmisison experiments provided evidence that the causative agent probably was not transmitted to the majority of the persons at the camp by air, fomites, biting insects, food, milk, the lake water or directly from infected persons. On the basis of the epidemiologic observations alone, water from the well in the girls' section appeared to be the only potential carrier of the infectious agent that could satisfactorily explain the outstanding characteristics of the epidemic. The transmission experiments showed that the hepatitis agent was excreted in feces, and the bacteriologic studies provided evidence of fecal contamination of the girls' well water. Finally, the transmission experiments provided experimental evidence that this water contained a transmissible agent which was probably the same as that excreted in the feces of the camp patients. The data provided by the epidemiologic observations, the bacteriologic studies and the transmission experiments in volunteers all lead to the conclusion that the infectious agent was transmitted to the majority of the cases at the camp by water from the girls' well. The source from which the well water was contaminated with the hepatitis agent was not demonstrated, but the available evidence indicates that the source was a cesspool, located near the well, which received the excreta from 1 or more infected persons almost continuously after the first day of the camp season.

CONCLUSIONS

1. The evidence indicates that the agent responsible for this epidemic was water borne.

2. The causative agent of infectious hepatitis is excreted in the feces of persons with the disease. The evidence presented herein confirms the observations of others in this respect.

3. Anything subject to direct or indirect contamination with feces provides a potential means of transmission of this disease.

4. This appears to be the first epidemic of infectious hepatitis (not homologous serum hepatitis) in which experimental evidence of the method of transmission has been obtained. As far as known, this also appears to be the first satisfactory evidence of the natural transmission to man of any virus agent by water.

DISINFECTION OF WATER CONTAINING CAUSATIVE AGENT OF INFECTIOUS (EPIDEMIC) HEPATITIS

During the past few years the incidence of infectious (epidemic) hepatitis has increased to such an extent that the disease has become one of the most serious medical problems of the present war. The development of effective methods for its prevention and control has been prevented by the lack of definite knowledge concerning the sources of the causative agent and the factors involved in its transmission. However, recent investigations [1] have shown that the causative agent is excreted in the feces of infected persons. This has suggested that feces may be a common source of the agent and that anything subject to fecal contamination may be a potential means of transmission of the disease. More recently, evidence has been obtained that the agent from feces may be transmitted by drinking water.[2] It has seemed important, therefore, to determine the effect on the hepatitis agent of methods commonly used for the disinfection of drinking water. For this reason, an initial experiment concerned with the effect on the hepatitis agent of a concentration of chlorine commonly used for the emergency disinfection of drinking water was conducted. Because the results showed that the hepatitis agent was not destroyed by this treatment, the effect of a higher concentration of chlorine was tested. Also an attempt was made to remove the agent from contaminated water by coagulation and adsorption with sodium carbonate, aluminum sulfate and activated carbon. The present report deals with the methods and results of these investigations.

MATERIALS

EXPERIMENT A (*Effect of Chlorination*).—Ten cc. of a 10 per cent feces suspension (pool 1 FIH), known to contain the agent of infectious hepatitis and described in detail elsewhere,[2] was added to each of two bottles (water specimens 1 and 2) containing 18,000 cc. of distilled water. Each water specimen thus contained approximately 55 parts of feces per million parts of water.

1. Water Specimen 1: This water was not subjected to further treatment.

2. Water Specimen 2: This was treated with chlorine in accordance with a technic commonly used for the rapid disinfection of drinking water under emergency conditions. The technic requires the addition of sufficient chlorine to provide a residual chlorine concentration of 1 part per million after a contact period of thirty minutes. The procedure was carried out as follows:

The chlorine demand of the contaminated water was determined by testing a number of portions for residual chlorine (starch-potassium iodide method; titration with sodium thiosulfate) thirty minutes after the addition of varying amounts of chlorine. The amount required to provide a chlorine residual of 1 part per million after thirty minutes' contact with this water was found to be approximately 2.5 parts per million. Accordingly, 2.5 parts per million of available chlorine (90 cc. of a chlorine solution prepared by dissolving grade A calcium hypochlorite in distilled water and standardized so as to contain 500 parts per million of available chlorine) were added to the 18,000 cc. of contaminated water. Thorough mixing was accomplished by rotation and agitation. The chlorine residual in this water after the thirty minute contact period was 1.08 parts per million.

The results of experiment A indicated the need for additional investigations. For this reason experiments B and C were carried out. The latter were started about four weeks after experiment A was completed.

EXPERIMENT B (*Effect of Superchlorination*).—To each of three bottles (water specimens 3, 4 and 5) containing 19,000 cc. of distilled water, 10.5 cc. of the same feces suspension [3] was added. Each water specimen thus contained approximately 55 parts of feces per million parts of distilled water. Two cc. of a suspension of Escherichia coli in isotonic solution of sodium chloride also was added to the contents of each bottle so that this organism could be used as an index of the effect on bacteria of the subsequent treatment of the specimens. The contaminated specimens were mixed thoroughly by rotation and agitation and then were allowed to stand for twenty-four hours at room temperature. Portions removed from each specimen then were pooled. Portions of this untreated pooled specimen were used for chemical and bacteriologic tests, for coagulation studies (unstrained portion) and for preliminary chlorine demand tests (strained portion). The subsequent treatment of the three specimens was as follows:

1. Water Specimen 3. Twenty-four hours after preparation, the specimen again was mixed thoroughly and then was strained through several layers of gauze and cotton. This constituted the only treatment of the specimen. The final strained water was opalescent and had a faint brown color and a strong hydrogen sulfide odor. Chemical studies showed that the straining process had resulted in a 32 per cent decrease in the concentration of organic solids and a slight decrease in turbidity.

2. Water Specimen 5: Twenty-four hours after its preparation, this specimen was strained through several layers of gauze and cotton. Chlorine demand and chlorine residual experiments on an untreated strained portion of the pooled specimen indicated that a concentration of approximately 25 parts per million of chlorine in the specimen would be required to oxidize completely all of the substances having a demand for chlorine, as shown by the "breakpoint" on a chlorine dosage-chlorine residual curve. Accordingly, sufficient chlorine (930 cc. of freshly prepared calcium hypochlorite solution standardized to contain 500 parts per million of available chlorine) to provide the 18.6 liter specimen with 25 parts per million of available chlorine was added and thoroughly mixed

From the Department of Pediatrics, University of Pennsylvania School of Medicine, and the Hospital of the University of Pennsylvania.
This investigation was conducted under the Commission on Measles and Mumps, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, Washington, D. C.
This investigation was made possible by the cooperation of the administrative staffs of Selective Service (Camp Operations Division), the National Service Board for Religious Objectors and the American Friends Service Committee. Invaluable assistance also was rendered by Mrs. Carolyn Rudd, R.N., and by members of the laboratory staff: Misses Dorothy Feinberg, Arvilla Howley, Catherine Fowler, Alda Ruth Johnson, Mrs. Jean Flick and Mrs. Alberta Hartman. Members of Civilian Public Service Unit 140 (Philadelphia) served as experimental subjects and other members of the unit assisted materially in the conduct of the investigation.

3. This preparation, feces pool 1 FIH, was stored at — 5 to — 20 C. between the experiments.

with the water. After a thirty minute contact period the chlorine residual was found to be 15.23 parts per million. This indicated that approximately 0.25 Gm. of available chlorine was contained in the remaining 16.6 liter specimen after withdrawal of samples for chemical tests and bacteriologic examination. Since this concentration of chlorine in drinking water would not be tolerated, the specimen was dechlorinated as promptly as possible, after the thirty minute contact period, by the addition of 0.44 Gm. of sodium sulfite. This quantity of sodium sulfite was based on the requirement of 1.78 parts by weight of sodium sulfite for the neutralization of 1 part of chlorine. The sodium sulfite immediately reduced the chlorine residual to less than 1 part per million, and this was accomplished within forty-five minutes after the chlorine had been added. Additional small quantities (not measured) of sodium sulfite were introduced until the residual chlorine was completely neutralized. Complete dechlorination of the specimen was accomplished within sixty minutes after the chlorine had been added, completing the treatment of this water. The final specimen was colorless but had about the same degree of opalescence as water specimen 3.

The concentration of total organic solids and the turbidity of this specimen were approximately the same as those of specimen 3, indicating that the changes, as compared with the untreated pooled specimen, were due chiefly to the straining procedure. The treatment did decolorize the specimen and lowered the p_H from 6.7 to 6.52.

EXPERIMENT C (*Effect of Coagulation and Adsorption*).—A commonly used method for removing extraneous materials from drinking water involves coagulation of the water by sodium carbonate and aluminum sulfate. For this reason water specimen 4, twenty-four hours after its preparation, was coagulated[4] by adding 166 cc. of a solution of sodium carbonate containing 1.712 Gm. per 500 cc. and 332 cc. of a solution of aluminum sulfate containing 1.712 Gm. per 500 cc. These amounts provided the 16.6 liter specimen with 2.0 and 4.0 grains (0.13 and 0.26 Gm.) per gallon respectively of sodium carbonate and aluminum sulfate. The sodium carbonate was added first, and after thorough mixing the aluminum sulfate was introduced. Because of the possibility that activated carbon might aid in the removal of the hepatitis agent, 0.415 Gm. (equivalent to 25 parts per million in 16.6 liters) of activated carbon (Nuchar C-115) was added immediately after the aluminum sulfate and before the latter was mixed thoroughly with the water. The specimen then was agitated gently by rolling the bottle for approximately fifteen minutes. This distributed the carbon particles evenly throughout the mixture. A heavy flocculum, to which the carbon particles became attached, gradually formed and began to settle. The specimen was permitted to stand without disturbance for one hour. By that time all of the flocculated material and carbon had settled to the bottom of the bottle. The supernatant then was removed by a sterile siphon apparatus and was strained through a sterile gauze and cotton "filter" into a sterile bottle. This completed the treatment of the specimen. The strained supernatant was clear, colorless and odorless.

The chemical studies on water specimen 4 showed that coagulation and adsorption by means of the sodium carbonate-aluminum sulfate-activated carbon treatment, followed by sedimentation and straining, had removed 85 per cent of the total organic solids and had eliminated the turbidity, leaving the water crystal clear in appearance. The treatment also lowered the p_H of the specimen from 6.7 to 6.44.

Bacteriologic Studies on Water Specimens 3, 4 and 5.—These consisted of presumptive and confirmatory tests for Escherichia coli and total 37 C. bacterial counts (twenty-four hours) conducted according to a standard technic.[5] Presumptive tests for Escherichia coli in the untreated pooled specimen and in specimens 3 and 4 were positive, 40, 25 and 30 per cent gas formation being observed after twenty-four hours in the lactose fermentation tubes inoculated with 0.1 cc. of the respective specimens. Positive evidence of the presence of Escherichia coli in this portion of the three specimens was shown on confirmed and completed tests. The bacteria were so numerous that it was not possible to count the number of colonies developing after twenty-four hours at 37 C. on plates inoculated with 1 cc. of the three specimens. This would suggest that the sodium carbonate-aluminum sulfate-activated carbon treatment had failed to decrease the concentration of Escherichia coli. However, 37 C. bacterial counts on dilutions of this specimen were not made and a considerable decrease in bacterial count could have occurred without being apparent in the test of the undiluted water.

No bacterial growth was obtained in lactose tubes or on plates inoculated with water specimen 5, indicating that the bacteria had been destroyed by the chlorination procedure.

No bacterial studies of water specimens 1 and 2 were made at the time they were prepared and consumed. However, in order to obtain information concerning the effect on bacteria of treatment similar to that of water specimen 2, a portion of the untreated pooled specimen was treated with 2.5 parts per million of chlorine. After thirty minutes' contact, the chlorine residual was found to be 0.74 part per million. The presumptive test on this specimen was positive, the lactose tube inoculated with 0.1 cc. showing 60 per cent gas formation after twenty-four hours. However, the confirmatory test for Escherichia coli was negative, and the 37 C. count showed only four colonies per cubic centimeter of the undiluted specimen. No colonies developed on the plate inoculated with 1 cc. of a 1 to 10 dilution of the specimen. This specimen differed from water specimen 2 in that the former was inoculated with 2 cc. of a suspension of Escherichia coli in addition to the feces suspension and then was allowed to stand for twenty-four hours. The difference in thirty minute chlorine residuals in this and water specimen 2, 0.74 part per million and 1.08 parts per million respectively, probably was due to the development of a greater chloride demand with standing. The findings that the treatment of this specimen with 2.5 parts per million of chlorine apparently destroyed the Escherichia coli organisms and greatly reduced the bacterial count indicate the probable effect of this treatment on the bacteria in water specimen 2.

METHODS

The only known method of determining the presence of the hepatitis agent in a given material is by demonstrating the ability of that material to produce hepatitis in human volunteers. Thus the effect on the hepatitis agent of the water treatment was estimated by comparing the incidence, incubation periods and severity of hepatitis following the ingestion of the treated water by volunteers with the same factors following the ingestion of untreated water by other volunteers (controls).

Volunteers.—The volunteers selected as subjects for these experiments were all under 33 years of age. They had no previous history of jaundice and no evidence of liver dysfunction detectable by history, physical examination and liver function tests.

4. The amounts of sodium carbonate and aluminum sulfate required for satisfactory coagulation of the water were determined by tests on the untreated pooled specimen.

5. American Public Health Association: Standard Methods of Water and Sewage Analysis.

Inoculation of Volunteers.—The various water specimens were administered to groups of volunteers as follows:

1. EXPERIMENT A.—Forty minutes after the chlorine solution had been added, 400 cc. of water specimen 2 was ingested by each of 5 healthy male volunteers (group II). At the same time 400 cc. of water specimen 1 (untreated) was ingested by each of 5 other healthy male volunteers (group I). During a period of thirty-six hours a total of 3,600 cc. of the appropriate water was ingested, under supervision, by each subject.

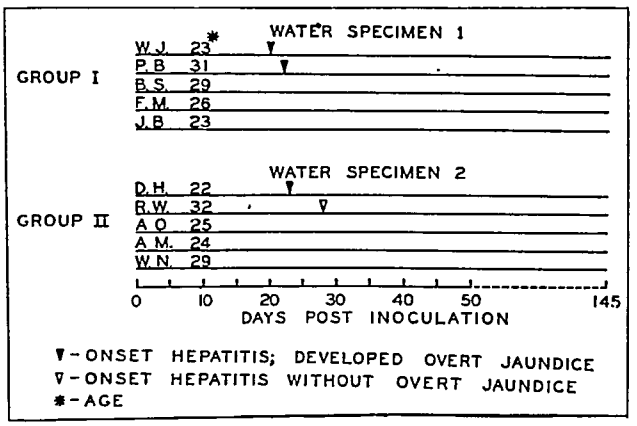

Chart 1.—Incidence and time of onset of hepatitis in volunteers after ingestion of water specimens.

2. EXPERIMENT B.—Twenty-eight hours after its preparation and four hours after it was strained, 400 cc. of water specimen 3 was ingested by each of 5 male volunteers (group III). Thirty-two hours after its preparation and fifteen minutes after it had been completely dechlorinated, 400 cc. of water specimen 5 was ingested by each of 5 male volunteers (group V). During a period of twenty-four hours, each of the volunteers in groups III and V ingested, under supervision, a total of 2,900 cc. and 2,800 cc. respectively of the appropriate water.

3. EXPERIMENT C.—Twenty-nine hours after its preparation and two hours after sedimentation following the addition of the sodium carbonate-aluminum sulfate-activated carbon mixture, 400 cc. of water specimen 4 (strained supernatant) was ingested by each of 5 male volunteers (group IV). During a period of twenty-four hours the men of group IV ingested a total of 2,725 cc. of water specimen 4. Group III served as the control group for both groups IV and V.

Isolation of Volunteers.—The various groups of volunteers were isolated from one another, and from other persons, during and after the period of inoculation; however, the members of each group were not isolated from one another. The groups were confined to separate quarters and had separate dining rooms, eating utensils and toilet facilities. No articles were exchanged between the groups.

Detection of Hepatitis.—Each subject was studied at frequent intervals by means of the group of liver function tests described elsewhere.[6] These studies had been conducted at frequent intervals during a three to six week preinoculation period in order to establish, as far as possible, the physiologic variation in the response of each person to each of these tests. After inoculation, all subjects were observed closely for symptoms and signs of any illness and the liver function tests were performed two or more times weekly. Temperatures were taken twice daily.

6. Neefe, J. R.; Stokes, J. Jr.; Reinhold, J. G., and Lukens, F. D. W.: Hepatitis Due to Injection of Homologous Blood Products in Human Volunteers, J. Clin. Investigation **23**: 836 (Sept.) 1944.

RESULTS.

Effect of Chlorination (Experiment A).—As shown in chart 1, 2 of the 5 controls (group I) who ingested 3,600 cc. of water specimen 1 (untreated) developed infectious hepatitis[7] during the 4th week after inoculation. During the same period 2 of the 5 men (group II) who ingested 3,600 cc. of water specimen 2 (chlorinated) also developed infectious hepatitis. Three of the 4 men who contracted hepatitis had moderately severe jaundice. The 4th (R. W.), who had received chlorinated water, did not develop overt jaundice, but the occurrence of typical symptoms and elevation of temperature to 102 F., strongly positive tests for bilirubin in the urine, 43 per cent retention of sulfobromophthalein after forty-five minutes, a 4 plus cephalin flocculation reaction and a significant decrease in the concentration of esterified serum cholesterol confirmed the diagnosis of hepatitis in this case. Subject D. H. (chlorinated water) had slight elevations of temperature and mild symptoms of malaise, anorexia and abdominal discomfort periodically after the 8th postinoculation day. On the 23d day acute symptoms and signs of the infection suddenly developed. These included a chill, an oral temperature of 104 F., a scarlatiniform rash, abdominal pain, anorexia, nausea and vomiting. By the 27th day he was obviously jaundiced. It is of interest that the earliest, and subsequently the most severe, manifestations occurred in this volunteer who had received the chlorinated water.

Effect of Superchlorination (Experiment B).—Four of the 5 controls (group III) who ingested 2,900 cc. of water specimen 3 (untreated except for straining) developed moderately severe infectious hepatitis after incubation periods of 19, 19, 19 and 22 days (chart 2). All of these 4 men developed overt jaundice. The highest total bilirubin concentration in each was 6.3, 7.2, 9.3 and 10.2 mg. per hundred cubic centimeters of serum. All had moderate to pronounced liver tenderness during the active disease. The 5th man in this group has shown no clinical or laboratory manifestations of hepatitis during the 80 days which have elapsed since ingestion of the water.

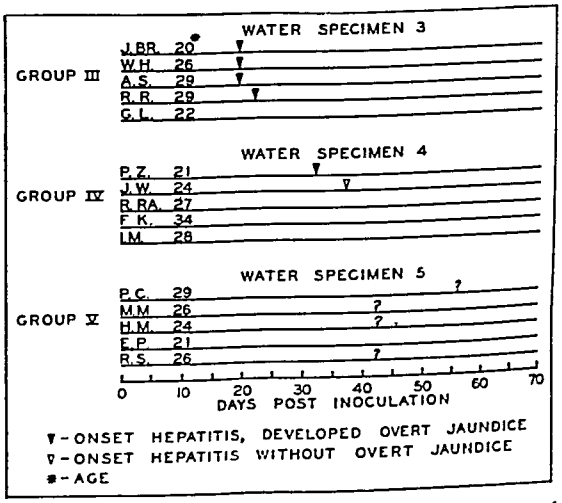

Chart 2.—Incidence and time of onset of hepatitis in volunteers after ingestion of water specimens.

7. The diagnosis of infectious hepatitis was based on the occurrence of typical symptoms and signs of the disease in association with typical changes in the responses to the various liver function tests.

None of the 5 men (group V) who ingested 2,800 cc. of water specimen 5 (superchlorinated, then dechlorinated) have had symptoms or physical signs of any illness during the 80 days which have elapsed.

However, serums obtained from subject H. M. on the 42d, 49th, 52d, 53d, 57th, 64th and 67th days gave cephalin cholesterol flocculation reactions of 2+/3+,[8] 1+/2+, ±/2+, 2+/2+, ±/2+, 2+/3+ and 2+/3+ respectively. Six tests performed on different days during a three week preinoculation period gave readings of 0/±, 0/0, 0/1+, 0/0, 0/0 and 0/0 respectively. During the postinoculation period all the other liver function tests performed in association with the cephalin tests gave normal results.

Serums obtained from subject M. M. on the 42d, 49th, 59th and 67th days gave cephalin cholesterol flocculation readings of 0/1+, 0/1+, ±/3+ and 1+/2+ respectively. Twenty tests performed on different days prior to the 42d day had given negative readings at both twenty-four and forty-eight hours. On the 56th day the serum esterified cholesterol constituted 39 per cent of the total cholesterol. With several previous determinations the esterified fraction had constituted 57 to 68 per cent of the total cholesterol. The other tests of liver function have shown no abnormalities during the eighty days which have elapsed.

Serums obtained from subject R. S. on the 42d, 59th and 67th days gave cephalin flocculation readings of 0/1+, 0/1+ and 1+/2+ respectively. Many previous cephalin tests had shown no flocculation. The other tests of liver function showed no abnormalities during the postinoculation period.

Serum obtained from subject P. C. on the 56th day gave a cephalin cholesterol flocculation reading of 2+ at forty-eight hours. All previous and subsequent cephalin tests were negative. The other tests of liver function revealed no abnormalities during the postinoculation period.

Subject E. P. has shown no clinical or laboratory manifestations of any illness during the eighty days which have elapsed to date.

Effect of Coagulation-Adsorption (Experiment C).—Two of the 5 men (group IV) who received 2,725 cc. of water specimen 4 (treated with sodium carbonate, aluminum sulfate and activated carbon) developed mild infectious hepatitis after incubation periods of thirty-three and thirty-seven days (chart 2).

Mild symptoms and fever appeared in subject P. Z. on the 33d day, but the diagnosis of hepatitis could not be established until the 41st day, when bilirubinuria, sulfobromophthalein retention and cephalin cholesterol flocculation simultaneously appeared. Although his total serum bilirubin concentration never exceeded 1.9 mg. per cubic centimeter, the other tests of hepatic function revealed the presence of considerable hepatic disturbance as indicated by (*a*) bilirubinuria 4+, (*b*) sulfobromophthalein retention 42 per cent at forty-five minutes, (*c*) cephalin cholesterol flocculation 4+, (*d*) serum colloidol gold reaction 4+, (*e*) thymol turbidity test 10 units, (*f*) serum esterified cholesterol 36 mg. per hundred cubic centimeters (15 per cent of total). Faint scleral icterus was observed for a few days, but no tenderness or enlargement of the liver was detected at any time. The only significant gastrointestinal symptom was anorexia. Nausea and vomiting did not occur. The most prominent symptoms were malaise and headache associated with mild pain in the eyeballs on movement. At the onset, his temperature reached 103 F. (oral), but it returned to normal within thirty-six hours and remained normal thereafter.

The symptoms and signs in subject J. W. were even less pronounced that those of P. Z. On the 37th day he developed slight malaise, anorexia, vague abdominal discomfort, slight headache, mild diarrhea and an elevation of temperature to 100 F. (oral). The headache, fever and diarrhea persisted only twenty-four hours, but the malaise, anorexia and vague abdominal discomfort lasted for approximately ten days. No abnormal physical findings were detected at any time. During the illness, the cephalin cholesterol flocculation test gave responses varying from 1 to 3+ (previously always negative), the thymol turbidity test gave a reading of 3 units (highest previous reading was 1.5 units) and the concentration of esterified serum cholesterol decreased to 29 per cent of the total cholesterol (previously 53 to 63 per cent of the total). The other tests of liver function showed no significant abnormalities.

No significant clinical or laboratory abnormalities have been observed in the other 3 men of this group during the eighty days which have elapsed.

8. 2+/3+ signifies the twenty four and forty-eight hour readings respectively.

COMMENT

In experiment A no significant differences in incidence, incubation period or severity of the disease were observed between the groups receiving the untreated and the chlorinated water. The results indicate, therefore, that this causative agent of infectious hepatitis was not inactivated or attenuated by a forty minute period of contact with sufficient chlorine to provide a residual chlorine concentration of 1 part per million after thirty minutes' contact. Thus this technic for emergency disinfection of drinking water does not assure protection against the agent of infectious hepatitis.

The results in group V (experiment B) indicate that superchlorination resulted in a definite attenuation of the hepatitis agent. None of the men ingesting the superchlorinated water have had symptoms or physical signs of any illness. However, between the 42d and 67th days after inoculation, positive cephalin cholesterol flocculation tests were obtained with serums from 4 of the 5 men. The significance of the positive tests under these conditions is most uncertain. Positive tests were not obtained with normal serums tested simultaneously, and no change was made in the technic of performing the test during this period. Thus the possibility that the positive tests in these men were due to subclinical hepatic disturbances, produced by an attenuated hepatitis agent, cannot be excluded. For this reason the results of this experiment do not permit the conclusion that the hepatitis agent was inactivated completely by superchlorination. However, the results do warrant the conclusion that the hepatitis agent, at the least, was much attenuated by superchlorination.

The results in group IV (experiment C) indicate that the hepatitis agent was not completely removed or inactivated by treatment of the contaminated water with sodium carbonate, aluminum sulfate and activated carbon. However, the incidence of hepatitis was lower, the incubation periods were longer and the disease was much less severe than in the control group (group III). Although the groups were too small for these differences to be conclusive, the differences were consistent. The results suggest, therefore, that the treatment procedure may have resulted in either or both a decrease in concentration and a decrease in virulence of the hepatitis agent. Previous studies [2] have afforded some evidence that a decrease in the amount of orally administered hepatitis agent does not necessarily influence the severity of the disease but may result in a prolonga-

tion of the incubation period. Thus the mildness of the disease in the men of group IV may have been due to an attenuating effect of this treatment procedure on the hepatitis agent.

The results of these studies suggest that the control of the hepatitis agent in contaminated water may require modification of certain methods commonly used for water disinfection. They also suggest that the methods used may affect the concentration and the virulence of the hepatitis agent. These effects may result in modification of the incubation period and the severity of the disease. The possible prolongation of the incubation period should be borne in mind in the interpretation of epidemiologic data. It also is possible that the ratio of icteric to nonicteric cases in epidemics due to water borne agents may be influenced by the treatment to which the water has been subjected.

SUMMARY

Three experiments (A, B and C) were conducted on the disinfection of water containing the causative agent of infectious hepatitis. In experiment A, 2 equal volumes of distilled water were contaminated with feces known to contain the causative agent of infectious (epidemic) hepatitis. One specimen (water specimen 2) was treated with sufficient chlorine to provide a chlorine residual of 1 part per million after thirty minutes' contact. The other specimen (water specimen 1) was not subjected to further treatment. Two of the 5 volunteers (control group) who ingested 3,600 cc. of the untreated water developed infectious hepatitis after incubation periods of twenty-one and twenty-three days. Two of the 5 volunteers who ingested 3,600 cc. of the chlorinated water developed infectious hepatitis, 1 with and 1 without overt jaundice, after incubation periods of twenty-three and twenty-eight days respectively.

The results of experiment A led to experiments B and C. Three equal volumes of distilled water were contaminated with feces containing the hepatitis agent as in experiment A. The only treatment of 1 specimen (water specimen 3) consisted in straining it through a gauze and cotton "filter." Another specimen (water specimen 5) after similar straining was treated with sufficient chlorine to reach the chlorine "breakpoint" and provide a chlorine residual of 15 parts per million after thirty minutes' contact (superchlorination). The remaining specimen (water specimen 4) was treated with sodium carbonate, aluminum sulfate and activated carbon; after settling, the supernatant was strained through gauze and cotton. Four of the 5 volunteers (control group) who ingested 2,900 cc. of water specimen 3 (untreated except for straining) developed moderately severe infectious hepatitis with overt jaundice after incubation periods of nineteen, nineteen, nineteen and twenty-two days. None of the 5 men ingesting 2,800 cc. of water specimen 5 (superchlorinated) have developed clinical symptoms or physical signs of hepatitis during the eighty days which have elapsed. However, 4 of the 5 men developed positive cephalin cholesterol flocculation tests between the 42d and 67th days after their inoculation. One of these 4 also showed a decrease in the concentration of esterified serum cholesterol. Other liver function tests revealed no other evidences of hepatic dysfunction at any time. Two of the 5 men who ingested 2,725 cc. of water specimen 4 developed mild infectious hepatitis, 1 with scleral jaundice and 1 without overt jaundice, after incubation periods of thirty-three and thirty-seven days respectively.

CONCLUSIONS

1. Treatment of contaminated water with sufficient chlorine to provide a chlorine residual of 1 part per million after thirty minutes' contact did not inactivate or attenuate the causative agent of infectious hepatitis.

2. Treatment of contaminated water with sufficient chlorine to provide a residual chlorine concentration of 15 parts per million after a thirty minute contact period resulted in a definite attenuation of the hepatitis agent.

3. Treatment of contaminated water with sodium carbonate, aluminum sulfate and activated carbon did not completely remove or inactivate the hepatitis agent. However, the treatment may have resulted in a decrease in concentration and possibly some decrease in virulence of this agent.

4. The concentration and/or virulence of the hepatitis agent in water may be so affected by these treatment procedures as to result in some modification of the disease produced. The available evidence suggests that a decrease in either or both concentration and virulence may be associated with a prolongation of the incubation period. A decrease in virulence also may be associated with a decrease in the severity of the disease.

5. The complete inactivation of the causative agent of infectious hepatitis in drinking water may require further modifications of methods used for water disinfection.

TOXIC EFFECTS OF DIODOQUIN

DANIEL N. SILVERMAN, M.D.
AND
ALAN LESLIE, M.D.
NEW ORLEANS

According to previously published reports of cases of amebic dysentery treated with diodoquin, the use of this drug has not been accompanied by any toxic or disagreeable symptoms. Craig,[1] in recommending the use of diodoquin for the prophylaxis of amebiasis, stated that ". . . *diodoquin is not accompanied* by any disagreeable symptoms, even when administered in large doses over a longer period of time." Silverman[2] reported 25 cases of acute and chronic amebic colitis and observed no toxic effects after a high dosage of twelve tablets a day. Hummel[3] treated 20 patients with nine tablets a day for twenty days without observing any evidence of toxicity. D'Antoni[4] made no mention of drug reaction in 84 cases of amebiasis treated with diodoquin. Bercovitz[5] in his recent textbook, referring to diodoquin, states that "the drug is nontoxic and nonirritating to the bowel mucosa." In view of such statements made by competent workers the following manufacturer's advertisement claim does not seem extravagant. In the G. D. Searle & Co. advertisement

appearing on page 9 of the advertisement section of the June 17, 1944 issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION this statement is made: "Whenever amebiasis is suspected, the high iodine amebicide . . . DIODOQUIN (5, 7-diiodo-8-hydroxyquinoline) . . . can be used without fear of untoward effects—its toxicity is negligible. . . . May be given in large doses over prolonged periods." In order to correct any misapprehension as to the absence of toxicity of this drug, without attempting to controvert its therapeutic efficacy, we believe that it is important to present 3 cases of toxic reactions following the administration of diodoquin, especially since these hitherto incontestable claims of freedom from toxicity have been made in THE JOURNAL, a medium widely circulated to the medical profession.

REPORT OF CASES

CASE 1.—P. F., a white man aged 52, admitted to the hospital with a six month history of bowel disturbance and with motile amebas in the stool, was given simultaneous emetine hydrochloride and diodoquin therapy, the former drug being administered intramuscularly in a dose of 30 mg. (½ grain) daily for five days only. Diodoquin was administered for nineteen days in a dosage of four tablets of 0.2 Gm. (3.2 grains) each three times a day. Shortly after chemotherapy was commenced the patient became asymptomatic. Eight days after discontinuation of the diodoquin, examination of the saline purged stool failed to reveal the presence of amebas. Twelve days later a furuncle appeared over the left temporal region. This furuncle ruptured spontaneously. Two months after the drug was stopped the patient returned with a recent history of two episodes of chills and fever and right upper quadrant distress. With a presumptive diagnosis of amebic hepatitis, and pending admission to the hospital, diodoquin was again prescribed in the same dosage as previously. Three days later a furuncle appeared over the left anterior superior iliac spine. This was incised and drained. The diodoquin was immediately discontinued, but two more furuncles, which ruptured spontaneously, made their appearance. Carbarsone was substituted for the diodoquin, and the emetine hydrochloride, which was started on admission to the hospital, was continued. Diarrhea which appeared was attributed to the carbarsone. This drug was discontinued, and the diarrhea subsided. At the time of discharge from the hospital the patient was asymptomatic. No amebas were seen in the saline purged stool, but it was thought that too little time had elapsed since the discontinuation of chemotherapy to warrant a definite statement as to the status of the patient.

CASE 2.—O. B. C., a white man aged 42, a pipefitter, had a history of "bowel trouble" of twenty years' duration. Stool examination revealed the presence of trophozoites of Ameba histolytica. Emetine hydrochloride and diodoquin therapy, as outlined in the first case, was instituted. The former was administered daily for four days. After eight days of diodoquin therapy the patient developed a severe generalized furunculosis necessitating multiple incisions and drainage. Although the drug was discontinued at once, the furunculosis persisted for a considerable time. Examination of the saline purged stool six months after therapy was discontinued failed to reveal the presence of amebas. The patient became asymptomatic, so despite the toxicoderma and short therapeutic course it is believed that a cure was obtained.

CASE 3.—M. R., a white woman aged 51, Spanish born, with amebic infection of the bowel, proved by feces examination, received twelve tablets of diodoquin daily for twenty-three days. The day after discontinuation of the drug the patient complained of sore throat and chilly sensations. A fine skin rash appeared; this rapidly developed into a blotchy erythema involving the entire body. The patient was readmitted to the hospital one week after completing the course of diodoquin. The temperature, which ranged up to 101.6 F. (oral), subsided after seven days of expectant treatment. Laboratory studies including blood culture showed no significant abnormality. The process subsided and the patient was discharged ten days after admission. One year later she was well and free from amebas.

COMMENT

In the first case no furuncles were observed except in association with diodoquin therapy, so it is reasonable to infer that a cause and effect relationship existed. Although the action of diodoquin is in the main topical, it is apparent that at least in certain inidviduals a sufficient degree of absorption takes place to result in what purported to be an iodine toxicoderma. This patient demonstrated a hypersensitivity not only to the iodine contained in diodoquin but to the arsenic contained in carbarsone and typifies the sort of drug sensitive individual not infrequently encountered. In the second case the role of diodoquin in the etiology of the furunculosis was so obvious as to leave little room for question. Of interest in this case was the apparently high iodine absorption and retention with delayed excretion from a preparation which is generally considered to be absorbed slightly or not at all. The type of reaction in the third case differed from those in the first two presented in that there was a systemic as well as a cutaneous toxicity exhibited and that the skin reaction was erythematous rather than pustular. We believe, however, that in this as well as the other cases idiosyncrasy to the iodine contained in the drug was the basis for the toxic manifestations.

The reason for the difference between the experience of other observers, as well as the early experience of one of us (D. N. S.), and the recent observations reported herein is not entirely clear. The dose originally recommended was one or two tablets of diodoquin three times daily. It was observed by Silverman that a larger dosage of the drug was required for maximum results. A dosage of three or four tablets three times a day was found to be effective in the eradication of amebas when the smaller dosage was not; this with no apparent introduction of toxic effects on the host. The element of statistical chance may account for the difference in question, for although the 3 cases were observed within a period of less than a year the overall incidence of toxic reactions is low. This report does not in any way attempt to negate the claims for the therapeutic efficacy of the drug in the treatment of amebiasis, since we as well as many others have used the drug with considerable success. It is, however, the desire to call attention to the possibility of symptoms of drug poisoning appearing during the treatment of amebiasis with diodoquin.

1521 Delachaise Street.

Development and Use of Cocaine.—The development and use of cocaine as a local anesthetic agent was chiefly the work of Carl Koller. When Koller was house surgeon at the Vienna General Hospital, his friend Sigmund Freud was studying the possibility of curing patients addicted to morphine by treating them with cocaine. Both Koller and Freud studied the physiologic aspects of cocaine. Freud turned his attention away from these investigations. Koller, however, continued his studies. He injected a weak solution of cocaine into the eye of a frog and noticed that the eye became insensitive to pain. On Sept. 15, 1884 Koller reported his observations to the Ophthalmological Congress held in Heidelberg. Soon afterward cocainization of the eye for the production of local anesthesia was generally adopted.—Keys, Thomas E.: The History of Surgical Anesthesia, New York, Schuman's, 1945.

LOEFFLER'S SYNDROME ASSOCIATED WITH CREEPING ERUPTION (CUTANEOUS HELMINTHIASIS)

LIEUTENANT COLONEL D. O. WRIGHT
AND
MAJOR EDWIN M. GOLD
MEDICAL CORPS, ARMY OF THE UNITED STATES

We have had the opportunity of observing 9 cases of creeping eruption in the dermatology wards and clinics of the Army Service Forces Regional Hospital, Camp Blanding, Florida, that have developed transient pulmonary infiltration during the course of their infection. A preliminary report of these observations is indicated since (*a*) standard textbooks [1] lead one to believe that this nematodal infection (usually Ancylostome braziliense) is a localized intradermal invasion; (*b*) a review of the available literature does not reveal a report of associated pulmonary involvement; (*c*) the clinical course, laboratory and x-ray findings are similar to the migratory pulmonary infiltrations with eosinophilia reported by Loeffler and others.[2]

The dermatologic manifestation of creeping eruption is an accepted clinical entity adequately described in standard textbooks. Kirby-Smith [3] suggested the nematodal origin of these lesions. The larvae wandering through the layers of the skin produce the serpiginous, elevated reddish tunnels that are characteristic of the disease. Dove and White [4] proved that the filariform larvae of Ancylostoma braziliense produce these lesions. The dog and cat are natural hosts for these nematodes and inoculate the soil with their feces. The filariform larvae remain viable for long periods in soil that is moist, sandy and shady, awaiting an opportunity for contact with the human skin.

During the past twelve months 26 cases of creeping eruption with classic cutaneous manifestations have been seen. Fifteen of these cases were observed for a period of fourteen days or more. Nine of these 15 cases during their period of observation demonstrated transient migratory, pulmonary infiltration, peripheral eosinophilia and paucity of clinical signs or symptoms of systemic disease, fulfilling the criteria of Loeffler's syndrome. In this series chest roentgenograms were made every three days for at least fourteen days. Our experience corroborates Loeffler's original observation that serial x-rays are necessary to detect the transient migratory pulmonary infiltration.

These 9 cases were afebrile during the entire period of observation. Physical findings were minimal. Slightly decreased resonance, roughened breath sounds and insignificant increase in the respiratory rate were the only positive findings. Rales were not heard at any time. Except for local skin irritation and a mild cough that occurred in only 4, these patients were not aware of any illness.

Differential counts on peripheral blood smears revealed an eosinophilia varying from 1 per cent to 32 per cent. The degree of eosinophilia roughly approximated the extent of the skin and pulmonary lesions and tended to persist after these lesions had subsided.

Roentgen examination of the chest revealed a patchy infiltration, transient and often migratory in nature, usually not appearing before the seventh day of the skin invasion. When erroneous diagnosis or procrastination in therapy of the local skin lesions occurred, the pulmonary infiltration continued a migratory course over a period of weeks.

Vital capacity studies performed in 5 cases on several occasions failed to reveal any diminution, though chest x-rays were positive at the time. This fact, together with lack of dyspnea and/or cyanosis, tends to support the contention that the infiltrative process is an interstitial one rather than a true alveolar exudative or atelectatic consolidation.

Sedimentation rates by the Wintrobe method repeated every three days on 5 of the 9 patients with pulmonary infiltration were within normal limits except in 2 cases complicated by secondary infection and cellulitis about the cutaneous lesions. The rate in these 2 cases returned to normal as soon as the secondary infection

subsided despite persistence of the pulmonary infiltration.

By persistent effort 8 patients produced 39 sputum specimens at some time during their illness. Eosinophil counts on these specimens varied from 2 per cent to 90 per cent.

53	8/ 6/44	23	..	Negative.....	4

Patient admitted with painful, itchy, weeping, secondarily infected serpiginous dermatitis typical of creeping eruption over buttocks. Lesions present fourteen days prior to admission. Mild cough developed day after admission.

Examination of 81 stool specimens from the 26 patients encompassing periods of observation from ten days to three months failed to reveal presence of ova or parasites in any specimen. This corroborates the findings of Smith, Dove and White and others that intestinal infestation by this nematode in the human being is rare.

Brunner [5] found in immunologic studies of human parasitic infections that Ascaris extract is representative of the nematode group. He also proved that intradermal testing with extracts of nematodal parasites had a practical value as a diagnostic aid in that positive reactions were indicative of past or present infestation. Because of these findings, Ascaris and Trichina extracts standardized for nitrogen content were used for intradermal testing in all cases. Positive results were obtained with at least one of these extracts in 23 of the 26 cases varying from 1 to 4 plus. No correlation between degree of skin test sensitivity and clinical findings was observed. Similarly no specificity as to reaction with Ascaris or Trichina extracts was noted.

Patient admitted on twenty-first day of disease with creeping eruption burrows over glutei, bilateral and on anterior abdominal wall. No cough. No sputum.

The migratory character of the pulmonary infiltration and the eosinophil variation in blood and sputum are summarized in 4 typical cases in tables 1 through 4.

COMMENT

The cases herein reported fulfil the criteria of Loeffler's syndrome predicated on the triad of a transient and migratory pulmonary infiltration, paucity of symptoms and physical signs and peripheral eosinophilia.

Similar findings have been reported associated with tuberculosis,[6] Ascaris infection,[7] Trichinosis,[8] asthma,[9] Malta fever,[10] Endameba histolytica infection [11] and pollinosis.[12] Such a diversified list of etiologic factors lends credence to the view that Loeffler's syndrome is an allergic phenomenon.

Additional proof of an allergic basis for Loeffler's syndrome and helpful points in its differential diagnosis from inflammatory lesions of the lung are peripheral and sputal eosinophilia, normal sedimentation rate, normal leukocyte count, absence of fever and systemic manifestations, migrating pulmonary infiltration, normal vital capacity and positive skin reactions to nematode antigens in cases associated with helminthiasis.

MENTAL AND PERSONALITY DISORDERS IN SELECTIVE SERVICE REGISTRANTS

COLONEL LEONARD G. ROWNTREE
MEDICAL RESERVE CORPS, UNITED STATES ARMY
KENNETH H. McGILL
AND
LOUIS P. HELLMAN
WASHINGTON, D. C.

The diagnosis of mental and personality disorders or serious potentialities for their development has resulted in the rejection of more Selective Service registrants than has any other defect. It must be understood that by mental and personality disorders is meant any variation in the emotional capacity of the individual to adjust to his situation which results in symptoms indicating, in this instance, the possibility of maladjustment to military life.[1] Among white registrants no other defects approach mental and personality disorders in importance as a cause for rejection, while for Negroes they are exceeded only by mental deficiency and syphilis. In addition, mental and personality disorders have accounted for more disability discharges from the armed forces than any other defects.

TABLE 1.—*Estimated Number of Registrants Aged 18-37 in Rejected Classes Because of Mental and Personality Disorders, Jan. 1, 1945* *

Race	Total Rejected	Rejected for Mental and Personality Disorders	
		Number	Per Cent of Total
All races	4,493,000	801,700	17.8
White †	3,621,000	708,000	19.6
Negro	872,000	93,700	10.7

* Includes those in class IV-F and also those transferred from class IV-F to the occupationally deferred classes, II-A(F), II B(F) and II C(F).
† Includes all races other than Negro.

The standards for the rejection or acceptance of men for military service have been the responsibility of the armed forces. Most of the rejections for mental and personality disorders have been made by psychiatrists at the armed forces' induction stations. However, the more serious cases such as those which have necessitated institutionalization have nearly always been rejected by Selective Service local board physicians; and during peacetime many of those with less serious mental and personality disorders were also rejected at local boards in accordance with the armed forces' physical standards.

From the Medical Division and the Division of Research and Statistics, National Headquarters, Selective Service System.

This report is based on sample studies of the results of examination recorded on DSS Forms 200, Reports of Physical Examination, for Selective Service registrants physically examined at local boards in peacetime, and DSS Forms 221, Reports of Physical Examination and Induction, for registrants examined at local boards and induction stations during wartime. Coverage of the sample studies varies from 10 to 25 per cent of the examinations.

1. Mental and educational deficiency are not included in this report. The major subdivisions of mental and personality disorders as used in this report were determined to a large extent by Medical Circular No. 1 revised by the Selective Service System May 19, 1941, which divided mental and personality disorders into five categories. They are (1) grave mental and personality disorders, such as schizophrenia (dementia precox), paranoia and their various manifestations, (2) major abnormalities of mood, such as abnormal fluctuations in mood and constant states of depression and elation, (3) psychopathic personality, including constitutional psychopathic inferiority characterized by the record of certain types of recurrent social, sexual or legal difficulties, (4) psychoneurosis, including hysteria, morbid anxiety, hypochondriasis and the so-called psychosomatic disorders such as gastrointestinal and cardiovascular disorders due primarily to mental and personality difficulties and (5) alcoholism and drug addiction, including psychoses due to these states.

NUMBER CURRENTLY REJECTED

On Jan. 1, 1945 an estimated 801,700, or 17.8 per cent of the 4,493,000 registrants aged 18-37 in the rejected classes, were so classified because of mental and personality disorders (table 1). This figure does not include the thousands of registrants rejected for such disorders at one time or another but who were later reexamined and either inducted into the armed forces or rejected for some reason other than mental and personality disorders. These defects accounted for a greater proportion of white registrants rejected than of Negroes.

More than 8 out of every 10 rejections for mental and personality disorders were due to psychoneurotic disorders or psychopathic personality. While most of the registrants rejected for these defects are not sufficiently incapacitated to prevent their following a useful vocation in civilian life, it was determined by Army and Navy medical examiners that military life would probably aggravate their condition. The remaining registrants who were rejected for mental and personality disorders had the more serious disorders or history of such conditions. It is estimated that approximately 30,000 of these had been rejected by local board physicians because of an obviously disqualifying mental or personality disorder. The basis for this disqualification was authentic information that the registrant had been under treatment or in an institution at one time or another.

REJECTION RATES FOR MENTAL AND PERSONALITY DISORDERS

Rejection rates for mental and personality disorders have increased with each successive year of Selective Service operations.[2] During 1940 and 1941 approximately 22 of every thousand registrants examined were rejected for this defect (table 2). In 1942 the rate increased to 50, in 1943 to 74 and in 1944 to 120 per thousand examined.

From November 1940 on, no appreciable changes have been made in the armed forces' actual standards for acceptance of men with mental and personality disorders as prescribed in Mobilization Regulations 1-9. However, with the gradual increase of psychiatrists on the staffs of armed forces' examining stations during wartime there was a stricter interpretation and application of the standards, which resulted in increased rejections for mental and personality disorders. In addition, three factors have operated to increase the rejection rate for mental and personality disorders. They are (1) changes in physical examination procedure, (2) lowering of standards in other defect categories and (3) actual increased nervous tension among the examined registrants as a result of the entry of the United States into the war and as the war progressed. These factors make it difficult to determine the effect of the changes in the ages of the examined registrants during each of the four years on the rejection rate for mental and personality disorders.[3]

The first two factors, which produced apparent but not real increases, were partially responsible for the

2. Additional data on rejection rates and the prevalence of mental and personality disorders are to be found in the following bulletins published by the Selective Service System: Medical Statistics Bulletin No. 1, Nov. 10, 1941, Medical Statistics Bulletin No. 2, Aug. 1, 1943 and Medical Statistics Bulletin No. 3, Nov. 1, 1944.

3. During 1940 and 1941 the majority of examined registrants were in the age group 21-35, in 1942 the age group was enlarged to 20-44; in 1943 and 1944 only registrants aged 18-37 were examined. During 1944, however, the average age of the examined registrants was lower than in 1943.

increase in the rate from 1940-1941 to 1942. During peacetime most of the registrants who were rejected were examined only by the general practitioner giving the local board examination, and comparatively few rejections were made for mental and personality disorders. Beginning in 1942 the local board physician gave only a screening examination, and most of the rejections were made after the induction station examination, which included an interview with a psychiatrist. The result was that the psychiatrist diagnosed many cases of mental and personality disorders which probably would have been missed by the general practitioner.

The second factor, the lowering of standards in other defect categories, operated with the first to produce an apparent increase in rejections for mental and personality disorders. Thus during peacetime tooth and eye standards were very high and tooth and eye defects were the leading causes for rejection. With the lowering of tooth and eye standards in 1942 the probability of being rejected for mental and personality disorders increased, since many registrants who would have been rejected for the more obvious tooth or eye defects also had mental and personality disorders of a disqualifying nature.

The third factor, increased nervous tension of registrants after the entry of the United States into the war, was partially responsible for the pronounced rise in the rejection rate for mental and personality disorders from 1942 through 1944. How much of the rise is due to this third factor is difficult to evaluate because of the changes in physical standards in other defect categories and the variations in the application and interpretation of the standards for mental and personality disorders. As the war progressed there was also the possibility that within the extremely limited time allotted for the psychiatric interview and the increasing efforts of the armed forces to maintain at a minimum discharges for psychiatric reasons, some psychiatrists may have been overcautious in excluding borderline cases from the armed forces.

For both races, rejection rates for mental and personality disorders increased with each succeeding year; the rate for Negroes increased more rapidly than for white registrants. In 1940-1941 and 1942 the Negro rates were 40 per cent and 60 per cent as great as the white rates. In 1943 and 1944 the rates for the two races were approximately equal. This greater increase for Negroes is mainly attributable to the fact that beginning in 1943 a greater proportion of Negroes were examined by psychiatrists than in 1942, as a result of the relaxed venereal standards.[4]

MAJOR SUBGROUPS OF MENTAL AND PERSONALITY DISORDERS

This section deals with the occurrence of the major subgroups of mental and personality disorders among all examined registrants whether or not they were rejected and as causes for rejection among rejected registrants only. The prevalence data afford a more nearly complete picture of the disorders than data on causes for rejection, since (1) in some cases registrants with mild mental or personality disorders such as transient psychoneurosis because of anxiety over the outcome of the examination were found acceptable for service if otherwise physically fit and (2) some registrants with both physical defects and mental and personality disorders were rejected primarily for physical defects and hence would not be counted in the rejections.[5]

During 1940 and 1941 approximately 26 out of every thousand white registrants examined were recorded as having some form of mental or personality disorder, while for Negroes the defect was found one third as often (table 3). Psychoneurotic disorders were the most frequent type of disorder recorded for both races —the bases for more than half of these diagnoses were functional disorders of expressive movements (tics, stammering, stuttering) and neurocirculatory asthenia. The prevalence rate for this defect among white registrants was more than four times that for Negroes. Psychopathic personality was next in order of importance, but the white rate was only twice the Negro rate.

TABLE 2.—*Estimated Rejection Rates for Mental and Personality Disorders by Race, 1940-1944* *

Year	All Races	White †	Negro
1940-1941	22.3	24.5	9.9
1942	49.6	52.4	32.4

* Corresponding data for induction stations are not available for the period 1940-1941.
† Includes all races other than Negro.

Studies made on obvious defects indicate that slightly less than one half of those diagnosed as having grave mental or personality disorders had been treated in hospitals for the mentally ill. In other words, the basis for the diagnoses in many of those "obvious" cases was an affidavit from a physician or a mental hospital.

Statements of institutional treatment for unspecified mental conditions and indefinite descriptions of mental or personality disorders are included in the subdivision "Mental and Personality Disorders Not Classifiable Elsewhere." More than one half of those so classified had "obvious" defects and in all likelihood had either a manic-depressive psychosis or schizophrenia or a history of one of these conditions.

The importance of the various subgroups as causes for rejection at local boards as shown in table 3 reveals that almost one half of the rejections were due to psychoneurotic disorders; the next largest groups were

4. In 1942 syphilis was the leading cause for rejection among Negroes, and the great majority of these rejections were based on local board screening examinations. During 1943 registrants with venereal diseases were inductible into the armed forces, so that registrants with these defects were forwarded to induction stations, where they received a psychiatric examination as part of the induction station routine.

5. Methods used in selecting the principal cause for rejection are explained in Edwards, T. I., and Hellman, L. P.: Methods Used in Processing Data from the Physical Examination Reports of the Selective Service System, J. A. Statistical A. 39: 165-182 (June) 1944.

mental and personality disorders not classifiable elsewhere and grave mental or personality disorders. Psychopathic personality ranked fourth in importance as a cause for rejection, in contrast to second place as a recorded defect among all examined registrants.

Psychoneurotic disorders accounted for only one third of the Negro rejections for mental and personality disorders, in contrast to one half for white registrants. A higher proportion of Negro than white rejections were for mental and personality disorders not classifiable elsewhere, psychopathic personality and chronic inebriety and drug addiction. In the case of psychopathic personality, particularly, the proportion of rejections for this defect among Negroes was twice as great as that among white registrants.

The prevalence of mental and personality disorders during 1942 and 1943 was 67.5 per thousand registrants examined (table 4). They were diagnosed relatively more frequently among white registrants than among Negroes. Psychoneurosis and psychopathic personality were the most frequently recorded mental and personality disorders. Psychopathic personality was the only subgroup which was recorded relatively more often for Negroes than for white registrants. The other specific mental and personality disorders, of a more serious nature, were found only one third as often among Negroes as among white registrants.

Psychoneurosis was the most frequent cause for rejection for mental and personality disorders among both races during 1942 and 1943, with psychopathic personality next in importance. Among white registrants, psychoneurosis accounted for twice as many rejections as psychopathic personality. Both defects were equally important as causes for rejection of Negroes, accounting for 9 out of every 10 rejections for mental and personality disorders. Grave mental or personality disorders, although next in importance, accounted for relatively few rejections among both races.

TABLE 4.—*Prevalence of Mental and Personality Disorders and Percentage Distribution of Rejections for These Defects Among Registrants Physically Examined at Local Boards and Induction Stations, 1942-1943*

Major Subgroup	Prevalence per 1,000 Examined			Per Cent Distribution of Rejections		
	All Races	White*	Negro	All Races	White*	Negro

Mental and personality disorders not classifiable elsewhere	1.5	1.6	1.3	1.8	1.8	1.7

* Includes all races other than Negro.

THE AGE FACTOR

In general, it can be stated that with increasing age the rejection rate for mental and personality disorders increased. However, the specific diagnoses differed in importance as causes for rejection when considered in relation to age. During 1944 the three leading diagnoses of mental and personality disorders were psychoneurosis, emotional instability and asocial and amoral trends. In addition, for the 18 year olds, emotional immaturity was one of the more important diagnoses.[6] The distribution of these diagnoses in relation to total mental and personality disorder rejections by age is shown in table 5.

The importance of psychoneurosis as a cause for rejection increased with increasing age—out of every hundred 18 year olds rejected for mental and personality

TABLE 5.—*Percentage of Mental and Personality Disorder Rejections Due to Selected Diagnoses, by Age* *

Age	Total	Psychoneurosis	Emotional Instability	Asocial and Amoral Trends	Emotional Immaturity	Other Mental

disorders approximately 30 were rejected for psychoneurosis, whereas the corresponding number among those 30 years of age and over was approximately 65. For emotional instability the situation was just the reverse—relatively more of the younger registrants rejected for mental and personality disorders had emotional instability diagnosed than the older registrants. With respect to asocial and amoral trends, relatively more of the rejections occurred among those under 25 than among those 25 and over. Emotional immaturity was the second leading diagnosis of mental and personality disorders among the 18 year olds, accounting for over one fifth of the mental rejections. As would be expected, its importance was negligible for those over 19 years of age. These age trends held for white registrants. Among Negroes, however, the only distinct age trends were for psychoneurosis and emotional immaturity.

Emotional immaturity and psychoneurosis accounted for a larger proportion of the mental rejections among white registrants, age for age, than among Negroes, while the reverse was true for emotional instability and asocial and amoral trends. The difference between the races was more pronounced with respect to asocial and amoral trends than for emotional instability.

THE OCCUPATIONAL FACTOR

The relationship of occupation and rejections for mental and personality disorders is shown in table 6. In evaluating these data it should be borne in mind that Selective Service policies with regard to occupational deferment have resulted in physical examination of relatively fewer men in some occupational groups than

6. Data on mental and personality disorders of 18 and 19 year old registrants examined during December 1942-February 1943 are included in Rowntree, L. G.; McGill, K. H., and Edwards, T. I.: Causes of Rejection and Incidence of Defects Among 18 and 19 Year Old Registrants, J. A. M. A. **123**: 181-185 (Sept. 25) 1943.

in others, and that, therefore, the occupational groups vary in their representativeness with respect to physical or mental condition. The farm group is probably the least representative of their group in the general population, owing to the passage of the Tydings Amendment, which deferred certain classes of agricultural workers. At the other extreme are the clerical, sales and service workers, and the emergency workers and unemployed.

Rejections for mental and personality disorders were highest among farmers and farm managers (143.4 per thousand examined) and emergency workers, unemployed and nonclassifiable (142.5). Students had the lowest rejection rate for this condition (72.9). The low rejection rate for students is probably due to their youth more than to any other factor.

Psychoneurosis rejection rates were highest for the professional and managerial and lowest for students. Farmers and farm managers had a rate 50 per cent higher than that for farm laborers. Rejections for reasons other than psychoneurosis were highest for the emergency workers, unemployed and nonclassifiable and lowest for professional and managerial. It can also be noted that farm laborers, students and emergency workers, unemployed and nonclassifiable were less apt to be rejected for psychoneurosis than for other mental conditions, which consist mainly of emotional instability and asocial and amoral trends, and that the reverse was true for all other occupations. In addition, a comparison of the rejection rate for craftsmen with that for operatives and laborers reveals a higher rejection rate for psychoneurosis and a lower rate for other mental disorders among the skilled workers than among the semiskilled and unskilled.

If only gainfully employed workers are considered (thus excluding students and the emergency worker group) it can be seen that professional and managerial workers had the highest psychoneurosis rejection rate and the lowest rate for all other mental conditions, while farm laborers had the lowest rate for psychoneurosis and the highest for all other mental conditions.

TABLE 6.—*Rejection Rates for Mental and Personality Disorders per Thousand Registrants Examined, by Occupation* *

Occupation	Total	Psychoneurosis	Mental and Personality Disorders Excluding Psychoneurosis
All occupations	113.1	63.0	50.1
Professional and managerial	109.9	85.2	24.7
Farmers and farm managers	143.4	80.9	62.5
Clerical, sales and service workers	106.4	67.9	38.5
Craftsmen	109.4	71.5	37.9
Operatives and laborers, except farm	111.0	60.6	50.4
Farm laborers	118.7	53.8	64.9
Students	72.9	32.1	40.8
Emergency workers, unemployed and nonclassifiable †	142.5	57.7	84.8

* Based on a sample of Reports of Physical Examination and Induction for registrants examined during November 1943-December 1943.
† Nonclassifiable constitute a negligible proportion of this group.

MEDICAL SURVEY PROGRAM

During the operation of the Selective Service System much information has been provided by the system bearing on the mental and personality status of registrants. This information has furnished the basis in many instances for acceptance or rejection of registrants by the armed forces. Prior to Oct. 4, 1943 many of the states developed some plan for obtaining medical and social histories of each registrant facing induction. On Oct. 4, 1943 a Medical Survey Program was initiated by the Selective Service System to coordinate and unify procedures for obtaining (1) additional medical and social histories on registrants classified or about to be classified into a class immediately available for service and (2) education histories from secondary schools for potential registrants 15 years of age and over and registrants classified or about to be classified into a class immediately available for service.[7]

Salient features of the medical survey program include (1) appointment on a voluntary basis of one or more persons in each local board area who are qualified to do health or social work as medical field agents and (2) procurement by the state director of educational histories of registrants for use by the induction stations. The medical field agents obtain medical and social histories of registrants from such sources as the registrant's personal physician, social service exchanges, hospitals and clinics and correctional institutions or agencies. At present there are more than 9,000 medical field agents, and medical survey information is being supplied for a substantial percentage of the registrants considered for induction.

SUMMARY

A review of prevalence and rejections for mental and personality disorders among Selective Service registrants shows that:

1. The majority of rejections for mental and personality disorders were made by armed forces' psychiatrists; these rejections were made on the basis of unfitness for military life, although not all the disorders were handicapping in civilian life.

2. Mental and personality disorders were the principal cause for rejection of 801,700, or approximately 17.8 per cent, of registrants aged 18-37 in rejected classes on Jan. 1, 1945.

3. The rejection rate for this type of disorder increased from 22.3 per thousand examined in peacetime to 120.2 per thousand examined in 1944.

4. The rise in the rejection rate was not solely due to increased nervous tension among examined registrants. Other factors to be considered are changes in examining procedure, lowering of standards in other defect categories and stricter interpretation of standards for mental and personality disorders by the armed forces' psychiatrists.

5. Relatively more white registrants than Negroes have been rejected for mental and personality disorders.

6. Psychoneurotic disorders and psychopathic personality account for more than 8 out of every 10 rejections for mental and personality disorders.

7. Psychopathic personality is more prevalent among Negroes than among white registrants, while the reverse is true for psychoneurosis.

8. With increasing age, relatively more registrants are rejected for psychoneurotic disorders.

9. Among 18 year olds more than one fifth of the rejections for mental and personality disorders are due to emotional immaturity.

10. Of those gainfully employed, the psychoneurosis rejection rate was highest for professional and managerial workers and lowest for farm laborers, while the rate for other mental and personality disorders (consisting mainly of emotional instability and asocial and amoral trends) was lowest for the former and highest for the latter.

7. Full details are given in Medical Circular No. 4, issued by the Selective Service System on Oct. 18, 1943.

THE USE OF FIBRIN FILM AS A DURAL SUBSTITUTE

AND IN THE PREVENTION OF MENINGOCEREBRAL ADHESIONS

FURTHER STUDIES AND CLINICAL RESULTS

FRANC D. INGRAHAM, M D
ORVILLE T. BAILEY, M D
AND
CULLY A. COBB JR, M D.
BOSTON

The need for a material which acts as a substitute for excised or injured dura mater and at the same time prevents meningocerebral adhesions has long been one of the most pressing in neurologic surgery. Numerous dural substitutes have been tried with varying degrees of success. On long-range study not one has proved adequate to fill these requirements.[1] In spite of this, the results secured when no material is employed have been so unsatisfactory that most neurosurgeons prefer to use one or another of the available dural substitutes, whatever their shortcomings may be.

In the course of a program devoted to the fractionation of human blood plasma,[2] large quantities of human

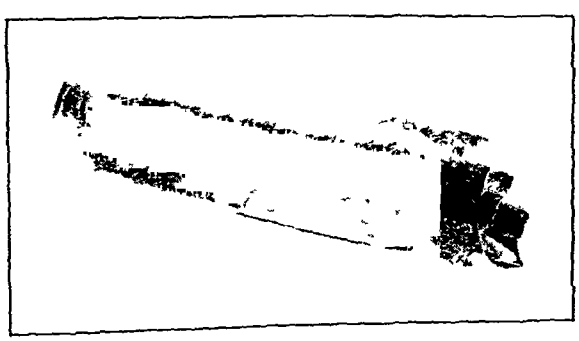

Fig 1.—Dry fibrin film after removal from the glass ampule

fibrinogen and thrombin have become available.[3] From these proteins it has been possible to prepare a material, fibrin film,[4] which has been subjected to experimental and clinical trial as a dural substitute.[5]

A variety of films may be prepared from solutions of thrombin and fibrinogen by varying the conditions under which clotting takes place and by changing the amount and character of the plasticizer present.[4] One type has been selected as most suitable as a dural substitute in physical properties and tissue reactions. It has been prepared with a low water content, so

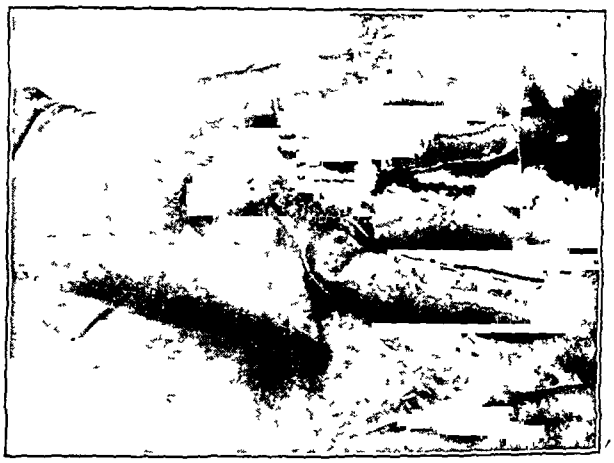

Fig 2.—Fibrin film after soaking in saline solution for fifteen minutes. It has become flexible and is easily handled

that it can safely be used a long time after distribution.[6] In this state fibrin film is translucent, firm and somewhat brittle when dry (fig. 1). After immersion in saline solution for fifteen minutes the physical properties are once more those of a moist membrane. The wet film is almost transparent but has become flexible (fig. 2) and elastic, returning to its original size and shape when stretched for 100 per cent of its length (fig. 3). Microscopic study of the fibrin film shows that it consists of a uniform sheet without interstices visible with oil immersion lenses. Diglycine passes through steam-sterilized fibrin film but hemoglobin does not.[7]

As prepared for distribution, fibrin film is packaged dry in a glass ampule (fig. 4). Sterilization has been

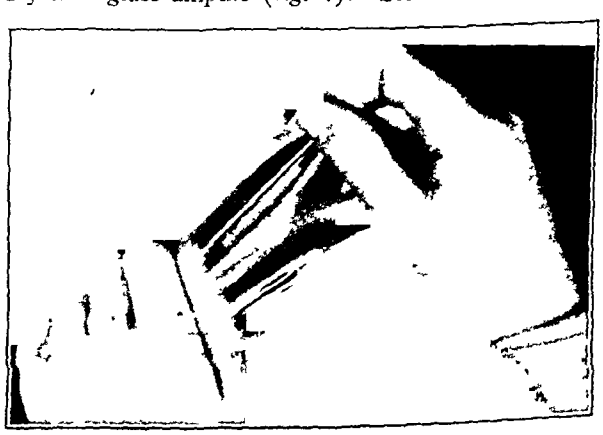

Fig 3.—Fibrin film is elastic

carried out in the ampule, and the fibrin film may not be resterilized.

ANIMAL EXPERIMENTS

When fibrin film first became available for trial as a dural substitute, sterilization was carried out in glycerol, a procedure practical on a small scale in the laboratory but cumbersome in large-scale production. Experiments with these films have been reported in detail elsewhere.[8]

After trying various methods of sterilization, it was found possible to sterilize fibrin film in the final container by steam under pressure.[6] Although films treated in this way were similar in physical properties to the glycerol-sterilized films, it seemed advisable to repeat the experimental studies before using steam-sterilized fibrin films on human patients.

The following procedure was carried out on 15 monkeys (Macaca mulatta):

After shaving the scalp, the field was cleansed with alcohol and zephiran. A midline incision was made in the scalp and a large temporoparietal decompression was performed on each side of the skull with sacrifice of the bone. On the left, a circular area of dura approximately 1.2 cm. in diameter was removed. A piece of fibrin film slightly larger than the dural defect (about 1.5 cm. in diameter) was placed over the intact arachnoid, the excess film being placed under the edges of the dura without suture. On the right the same

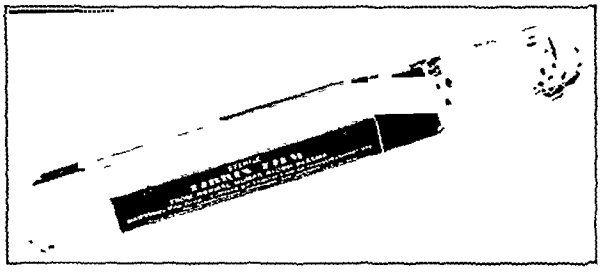

Fig. 4.—Unopened ampule of fibrin film.

procedure was carried out with the variation that in several areas a curved French needle was inserted through the leptomeninges into the outer layers of the cerebral cortex and then pulled out so as to lacerate the arachnoid, pia and the superficial cerebral tissues. The temporal muscles were closed over the fibrin films on both sides and the superficial tissues sutured with black silk.

The monkeys were killed at intervals of one day, two weeks and one, two, three, five and six months after operation. No abnormalities were noted in any of the monkeys during the survival period.

Pathologic studies indicated that the fibrin films were gradually replaced by a neomembrane of fibrous tissue without the formation of meningocerebral adhesions. In a few of the monkeys the fibrin film had slipped somewhat, so that a portion of the dural defect was covered by fibrin film and the rest by temporal muscle. Adhesions formed between the muscle and the arachnoid but did not form between the fibrin film and the arachnoid. Absorption of the fibrin film was almost complete at three months, and no film remained at five and six months after operation (fig. 5). The histologic sequences involved in the replacement of the steam-sterilized fibrin films were identical with those induced by glycerol-sterilized films; these have been discussed elsewhere.[8]

These experimental studies indicated that fibrin film as now distributed was safe for clinical trial as a dural substitute and in the prevention of meningocerebral

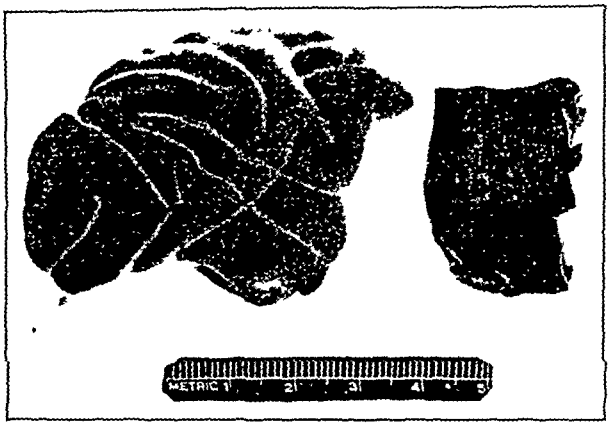

Fig. 5.—Brain of monkey six months after the use of fibrin film as a dural substitute. Note the absence of adhesions and the normal appearance of the cortical structures. At the right is the portion of dura in which a circular defect was covered by fibrin film. The neomembrane replacing the fibrin film blends with the dura and is almost indistinguishable from it.

adhesions. They also suggested that the experience gained from the use of the original films was applicable to the present material.

CLINICAL STUDIES

The clinical evaluation of any new material for use as a dural substitute is exceedingly difficult. Of the numerous substances suggested from time to time, experience has shown that favorable results may be obtained in a series of patients, only to be followed by untoward sequelae in other patients as the series is extended, or by late complications when the result had appeared at first satisfactory.[1]

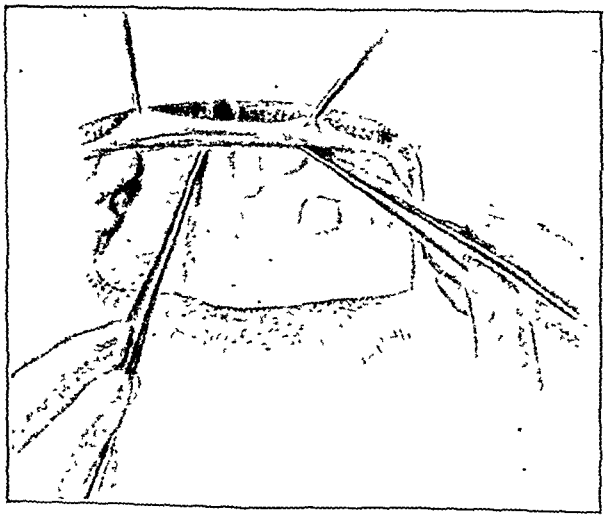

Fig. 6.—Technic used to hold the fibrin film in place without sutures. Although a portion of the cortex is shown uncovered by film in the drawing, a piece of fibrin film larger than the defect is used in the operation.

We have attempted to evaluate fibrin film as a dural substitute in the following ways: (1) by using it in as large a series of patients as possible, (2) by making use of it in many different types of neurosurgical procedures, (3) by following the patients until the fibrin film has been absorbed and (4) by studying

8. Ingraham, F. D., and Bailey, O. T.: The Use of Products Prepared from Human Fibrinogen and Human Thrombin in Neurosurgery: Fibrin Foams as Hemostatic Agents; Fibrin Films in Repair of Dural Defects and in Prevention of Meningocerebral Adhesions, J. Neurosurgery 1:23-39, 1944.

the films or regions in which they have been used at secondary operations or at necropsy. This report is based wholly on our personal experience.

The glycerol-sterilized films have been used as dural substitutes in 59 neurosurgical procedures and the steam-sterilized films in 35. Since the animal experiments suggest that the tissue reactions of the two types of films are very similar, it may be permitted to combine these figures, giving a total series of 94 instances in which fibrin film has been employed by us as a dural substitute and for the prevention of meningocerebral adhesions. This series would seem sufficiently large to give a definite indication of the advantages and limitations of the material.

Furthermore, the neurosurgical procedures have been carried out in the treatment of a variety of lesions (table 1) and in different regions of the central nervous system (table 2). They include operations for tumors of the brain and spinal cord, congenital malformations, degenerative diseases and traumatic lesions. The results have been uniformly favorable, regardless of the nature of the lesion which made advisable the use of a dural substitute. It should be pointed out that in the large majority of the patients fibrin film was used in a presumably sterile operative field. While

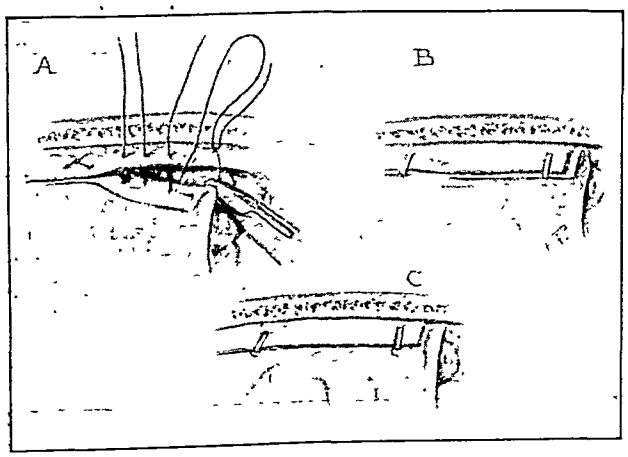

Fig. 7.—*A*, technic of suturing fibrin film; the cuff of film is easily sutured to the overlying dura. *B*, film held in place by applying widely spaced silver clips to the cuff. *C*, the fibrin film is held in place by inserting one prong of a silver clip through an opening in the fibrin film. While portions of uncovered cortex are shown in each of the drawings to illustrate the appearance of a cross section, a piece of fibrin film larger than the dural defect is used in the operating room.

it has been employed successfully in compound fractures, brain abscess and extradural abscess, our experience is not sufficient to make positive statements concerning the behavior of fibrin film in the presence of infection.

The crucial test of any dural substitute lies in the results sufficiently long after operation for the material to have been completely absorbed. As judged by animal experiments, fibrin film is largely removed in three months and completely removed in six months. As shown in table 2, 33 patients have been followed for six months or more after fibrin film was put in place as a dural substitute. All of them have remained free from symptoms referable to the fibrin film; in not a single instance have untoward sequelae developed. Furthermore, it has been evident that there was less cortical irritation as the result of the pathologic lesions present than would have been expected if no protective covering had been used.

As a final criterion, attempts have been made to study at secondary operation or at necropsy the site in which fibrin film had been placed. This has been possible in 19 patients in whom glycerol-sterilized fibrin film had been used, the times varying from fourteen hours to eighty-one days. The site of operation has also been studied a few hours to three months later in 8 instances in which steam-sterilized fibrin film had been left in place. Those recovered within two months after operation showed little change from their original appearance, and the underlying brain or spinal cord was not adherent to the fibrin film. In 1 patient a piece of steam-sterilized film was used to cover a large suboccipital defect created in an operation for medulloblastoma of the cerebellum, and another piece was wrapped about a Torkildsen tube put in during the procedure. At necropsy three months later the fibrin film over the cerebellum was completely absorbed; the arachnoid was smooth without adhesions to the neomembrane replacing the fibrin film. In portions of the operative field not covered by a dural substitute there were many dense adhesions. Some fibrin film was still present about the Torkildsen tube. It was thinner than it was at the time of operation but otherwise was unchanged in appearance and was not adherent to adjacent structures.

TABLE 1.—*Lesions Treated*

Diagnosis	Total Number	Glycerol Sterilized Film	Steam Sterilized Film	Duration <6 Mos.	Duration >6 Mos.
Skull fracture	5	3	2	3	2
Subdural hematoma	2	1	1	1	1
Jacksonian epilepsy	4	3	1	1	3
Brain abscess	2	1	1	2	0
Extradural abscess	1	1	0	0	1
Tuberculous meningitis	2	2	0	2	0
Chronic arachnoiditis	1	1	0	1	0
Encephalitis	1	0	1	1	0
Chronic progressive encephalopathy	2	1	1	2	0
Lead encephalitis	6	6	0	4	2
Arnold Chiari malformation	4	3	1	3	1
Spina bifida and cranium bifidum	9	3	6	6	3

Hydrocephalus	9	5	4	6	3
Tumors of brain and spinal cord	42	28	14	26	16
Total cases	94	59	35	61	33

TABLE 2.—*Location of Lesions*

Type of Film	Region	Total	Duration <1 Mo.	1-6 Mo.	6-12 Mo.	12-18 Mo.	18-24 Mo.
Glycerol sterilized	Frontal	6	1	1	0	2	2
	Parietal	22	8	3	2	5	4
	Temporal	14	5	2	0	2	5
	Occipital	3	1	1	0	1	0
	Posterior fossa	8	4	1	1	0	2
	Cervical cord	2	1	0	0	0	1
	Thoracic cord	3	0	1	0	0	2
	Lumbar cord	1	0	0	0	0	1
Steam sterilized	Frontal	5	1	4	0	0	0
	Parietal	3	1	1	1	0	0
	Temporal	8	1	7	0	0	0
	Posterior fossa	16	4	10	2	0	0
	Lumbar cord	3	0	3	0	0	0
Total		94	27	34	6	10	17

In view of these experiences, it would appear that fibrin film is the most satisfactory material now available for use as a dural substitute and in the prevention of meningocerebral adhesions.

TECHNICAL CONSIDERATIONS

Fibrin film is packaged in a glass tube (fig. 4), which should be kept in an ice box if possible, though it may be left at room temperature for many weeks without detectable evidence of deterioration. When

it is to be used as a dural substitute, the outside of the tube is sterilized by soaking in alcohol or other germicide. The tube is then washed with cool sterile saline solution (i. e. at room temperature) to remove any adherent germicide. The constricted band on the tube is scored with a file and the top struck sharply. Before the film is removed, the tube is filled with cool sterile saline solution and allowed to soak fifteen minutes. This is important because the film is brittle and difficult to handle when dry. After soaking, the film and paper wrapped about it are removed together by means of forceps. The paper is discarded and the film is immersed in cool saline solution until it is required. The film should not be allowed to dry at any time and must be kept well moistened even in the operative field. It should be used the same day the tube is opened.

At operation a piece is cut from the fibrin film corresponding in shape to the dural defect and somewhat larger than it. In the majority of instances it is not necessary to secure the fibrin film in place. A satisfactory result is obtained merely by placing the edges of the fibrin film carefully under the cut edge of the dura. (fig. 6). When dealing with a small defect or one in which the surgeon for any reason is concerned about displacement of the fibrin film, its position can be maintained by carefully placed mattress sutures. This procedure is best carried out by folding the edge and suturing the cuff thus obtained (fig. *7 A*). A cuff of the fibrin film may also be affixed to the dura by widely placed silver clips (fig. *7 B*). An alternative method is to make a small opening in the fibrin film and to insert one prong of a silver clip through it (fig. *7 C*). If sufficient care is used and the film is kept moist, the material is not difficult to suture or to clip, but if it is allowed to dry it is almost impossible to hold the fibrin film in place by any fixation method. It should be emphasized that instances requiring sutures or silver clips to hold the fibrin film in place are rare; in most instances, tucking an edge of the fibrin film under the dura gives the best results.

After the fibrin film is in place, the wound is closed by the same technic which would have been used had no dural substitute been employed.

COMMENT

Fibrin film has been shown to have the physical properties desirable in a dural substitute. In monkeys it not only leads to the formation of a neomembrane which forms a satisfactory protective covering but it also prevents the formation of meningocerebral adhesions. A thorough clinical trial indicates its safety and value in many locations and in the treatment of a variety of lesions.

While dural substitutes are required in a relatively small percentage of peacetime neurosurgical procedures, the situation is different in military neurosurgery. Reports indicate that the necessity of a dural substitute in head wounds is so great that the available materials, such as fascia lata and preserved human dura, are used even by those neurosurgeons who are well aware of the fact that the materials produce widespread meningocerebral adhesions. This is because they feel that the late clinical complications would be even more severe if no dural substitute was employed. These facts indicate that any dural substitute better than fascia lata or preserved human dura could be used by the armed forces to advantage.

The clinical and experimental studies of fibrin film show that it has great advantages over any other dural substitute now available. In addition it is prepared on a large scale; it is stable at ice box temperature for over a year and at room temperature for many months; it is easy to use in the operating room. It is still far too soon to assert that fibrin film is the ideal dural substitute; it does not seem too soon to state that it has important advantages over other dural substitutes now available.

SUMMARY

Fibrin film, prepared from human fibrinogen and thrombin, is now available for use as a dural substitute and in the prevention of meningocerebral adhesions.

Clinical and experimental studies indicate that it has many advantages over other dural substitutes now available.

TRANSFUSION OF O BLOOD

CONDITIONED BY THE ADDITION OF BLOOD GROUP SPECIFIC SUBSTANCES

FURTHER CLINICAL INVESTIGATIONS

NIELS C. KLENDSHOJ, M.D.
AND
ERNEST WITEBSKY, M.D.
BUFFALO

Group O blood has been used extensively as universal blood. Carefully investigated reactions to group O blood, published by workers with extensive experience in the field of blood transfusion, have caused many physicians to object to this method as a general procedure, granting that the Rh factor is given proper consideration as a source of reactions. It is reasonable to assume that isoagglutinins introduced into the circulation of human beings harboring the corresponding agglutinogens in the cells and plasma should combine with both, and it is a surprising fact that damaging reactions are not observed more frequently. Aubert, Boorman and Dodd [1] have demonstrated the occurrence of intravascular agglutination and hemolysis in a significant percentage of cases following the transfusion of serum of group O into recipients belonging to group A. On the basis of such observations the indiscriminate use of universal blood for transfusions into patients of different blood groups does not appear to us to be a recommendable procedure at present.

To overcome the objections to the use of group O blood with potent isoagglutinins as a universal blood, we have recommended the addition of the purified blood group specific substances A and B as a means of reducing the isoagglutinin titers to low levels.[2] In our early series of 147 cases [3] we were unable to demonstrate any untoward effect attributable to the addition of the blood group specific substances. A few of these patients received several transfusions at intervals of from ten days to three weeks.

From the Buffalo General Hospital and the Department of Bacteriology and Immunology, University of Buffalo School of Medicine.

2. Witebsky, E.; Klendshoj, N. C., and Swanson, P.: Preparation and Transfusion of Safe Universal Blood, J. A. M. A. **116**: 2654 (June 14) 1941.
3. Klendshoj, N. C.; McNeil, C.; Swanson, P., and Witebsky, E.: Transfusion of Conditioned Universal Blood, Arch. Int. Med. **70**: 1 (July) 1942.

To give further consideration to the problem of safety in conditioning of O blood with blood group specific substances, we have compared an additional series of 389 transfusions of O blood containing the purified group specific substances with 1,830 transfusions of homologous blood (belonging to the same blood group as the patient's blood) given under identical conditions. We added 5 to 10 cc. of a previously standardized solution of the blood group specific substances [4] to each pint of O blood either immediately before the transfusion was given or at the time the blood was made available for storage in the blood bank. The 389 transfusions of universal blood, conditioned by the addition of the A and B substances, were given without selection to recipients of all blood groups, frequently as an emergency procedure to avoid loss of time in typing and cross matching. We also prefer this method outside regular laboratory hours, as it eliminates the dangers inherent in blood matching by interns with limited experience in such work. Regarding specific technic, we refer to previous publications.[5]

Distribution of Reactions

Type of transfusion	Homologous		"Conditioned" Universal	
Total number of transfusions	1,830		389	
Reactions	No.	%	No.	%
Pyrogenic				
Grade 1	18	1	0	0
Grade 2	12	0.7	4	1
Grade 3	50	2.7	10	2.6
Hemolytic	5	0.3	0	0
Allergic	28	1.5	5	1.3
Circulatory	3	0.2	0	0
Undetermined	3	0.2	0	0
Total number of reactions	119	6.5	19	4.9

We have established a definite routine to secure recording of sufficient data for every transfusion on which classification of transfusion reactions may be based. For this purpose a special transfusion sheet is filled out by the house physician in charge of the transfusion and by the assisting nurse. Frequent determinations of temperature, pulse rate and blood pressure over a period of six to eight hours following transfusion are requested. In case of a reaction, determinations of icterus index, quantitative van den Bergh, cell counts and examinations of urine for hemoglobinuria are carried out routinely. The respective blood groups of donor and patient are rechecked and possible interference of the Rh factor is investigated. These determinations enable us in most instances to draw a conclusion as to the likely cause of the reactions.

We classify our transfusion reactions into five major groups according to suspected cause: pyrogenic, hemolytic, allergic, circulatory and undetermined.

Temperature reactions with no other untoward manifestations are recorded in the conventional group of pyrogenic reactions and subdivided into three grades: grade 1, a temperature rise of 1 to 2 degrees, grade 2, a rise of 2 to 3 degrees, and grade 3, a rise in temperature of more than 3 degrees or any reaction with a chill. In febrile cases we have excluded higher than normal temperatures as reactions to transfusions, unless comparison of temperature diagrams over a period of several days preceding and following the transfusion demonstrates definite deviation at the time of the transfusion from the patient's general temperature pattern.

The accompanying table shows the distribution of reactions in two groups: transfusions with homologous blood and transfusions with group O blood "conditioned" by the addition of the blood group specific substances A and B.

Comparison between the group of homologous blood transfusions with that of conditioned universal blood shows reaction rates of probable statistical identity. The hemolytic reactions which occurred only in the "homologous" group require comment. One of these reactions was due to administration of B blood to an O recipient by mistake as the result of an unfortunate similarity of names. The intern recognized his mistake before the transfusion had progressed very far. Of the remaining four hemolytic reactions three occurred in Rh negative patients, and there is good reason to believe that the Rh factor was responsible for these reactions. The ideal universal blood consists, therefore, in Rh negative O blood conditioned by the addition of blood group specific substances.

[illegible]ers have been found to increase in erroneous transfusion of incompatible blood. We have used intravenous injections of the purified blood group specific substances to increase isoagglutinin titers for purposes of producing potent typing serum.[6]

Theoretically the possibility exists that transfusion with "conditioned" universal blood might "sensitize" the patient to subsequent administrations of such blood or that even an initial transfusion of "conditioned" blood might cause untoward effects. It should be remembered that the specific substances A and B are added to O blood for the purpose of neutralizing the corresponding antibodies, and they are thus, presumably at least, partly present in combination with these antibodies. However, a biologic response on the part of the patient to injection of the combination is not necessarily excluded.

Further study of these points may be accomplished by a more detailed analysis of the reactions in the group of 389 conditioned universal blood transfusions, as recorded in the table. A total of 308 transfusions were given to patients who had had no previous exposure to the purified A and B substances. We encountered altogether 14 reactions in this group, distributed as follows: 3 (1 per cent) pyrogenic reactions, grade 2; 7 (2.3 per cent) reactions, grade 3, and 4 (1.3 per cent) allergic reactions. These reaction rates conform within statistical limitations to the general reaction rates for the homologous blood. The remaining 81 transfusions in the group of conditioned universal blood were administered to 48 patients who all had received previous transfusions of blood containing the purified A and B substances. The interval between these transfusions varied from a few days to several months. We encountered 5 reactions in these 81 transfusions corresponding to a total reaction rate of 6.2 per cent. The distribution of these reactions was as

6. Witebsky, E.; Klendshoj, N. C., and McNeil, C.: Potent Typing Sera Produced by Treatment of Donors with Isolated Blood Group Specific Substances, Proc. Soc. Exper. Biol. & Med. 55:167 (March) 1944.

follows: 1 pyrogenic grade 2, 3 pyrogenic grade 3 and 1 allergic. There are no significant differences in these rates and those obtained during the first transfusion of conditioned universal blood.

COMMENT

The problem of the safety of our transfusion procedure parallels in principle the question of transfusions of pooled plasma versus plasma of heterologous blood groups. Quantitatively the problem may be somewhat different, as the amounts of blood group specific substances we add are presumably large in proportion to the amounts naturally contained in plasma. Levine and State[7] reported that they had observed skin reactions to cutaneous injections of plasma derived from various groups. They attributed positive tests to the interaction of the group specific substances in plasma with the corresponding isoantibodies present in the circulation of the person tested, and they explained reactions following transfusion of plasma into persons exhibiting a positive skin test on the same basis as the skin test. To our knowledge their results have not been corroborated, and the explanation has not been accepted. The allergic nature of certain serum and plasma reactions seems to be satisfactorily explained by recent observations of Maunsell.[8]

SUMMARY

A series of 1,830 blood transfusions was compared with a series of 389 transfusions of group O blood to which group specific substances A and B had been added. Special attention was given to the classification and recording of blood transfusion reactions. In spite of rigid and critical observations, no harmful effect was observed attributable to the group specific substances employed. The addition of the purified specific substances A and B to O blood as a means of reducing the corresponding isoagglutinin titers to a low level can therefore be recommended as a safe and effective procedure.

The Idea of Big Numbers.—We know that one scientist may be worth ten thousand soldiers. The ancient Romans found it out when they attacked Syracuse in Sicily in 212 B. C. only to have their ships fired by burning glasses, smashed by stones from short and long range catapults, pulled out of the water and overturned by iron beaked cranes. All these fearful engines of war, not to mention such useful machines of peace as the water screw for irrigating land and pumping mines, the cogwheel and pulley for launching ships, were the inventions of an "absent minded" mathematician, Archimedes, who considered them "mere diversions of geometry at play." Whether or not he ran naked from his bath shouting "Eureka (I have found it)" on discovering that cunning goldsmiths had defrauded his relative King Gelon of Syracuse by substituting silver for gold in the king's crown, the fact remains that he did work out the laws of floating bodies and fluid displacement ("Archimedes' principle") on which the disclosure of such fraud depended. Among the other primarily mathematical, but later practical, problems which engaged his interest were the laws of the lever ("Give me a place to stand and I will move the earth") and the theory of big numbers, more important in a billion dollar modern world than when Archimedes anciently discussed it in "The Sand Reckoner."—The Autobiography of Science, edited by Forest Ray Moulton and Justus J. Schifferes, New York, Doubleday, Doran & Co., Inc., 1945.

HYPOPROTHROMBINEMIC ACTION OF QUININE SULFATE

LEO A. PIRK, PH.D.
NUTLEY, N. J.
AND
RECHA ENGELBERG, PH.D
NEW YORK

For some time we have been studying blood prothrombin levels in human beings. It seemed of particular interest to one of us (L. P.) to investigate the effect of certain drugs which are administered prophylactically or therapeutically over long periods on the prothrombin level. Among the most widely used compounds of this type are the antimalarials, and the present paper deals with the effect of quinine on the prothrombin time.

Five normal male subjects ranging in age from 18 to 43 years were chosen. Their nutritional state was satisfactory and they were advised to maintain a well balanced diet. The prothrombin time was normal in all instances. Two to four premedication controls, performed in each case, were in agreement within the range of normal variations. In carrying out the estimations the Page[1] method was used. According to this technic viper venom and calcium chloride are added to plasma obtained by centrifuging the decalcified venous blood. The very sharp end point is characterized by the formation of fibrin particles clearly visible in the agitated test tube.

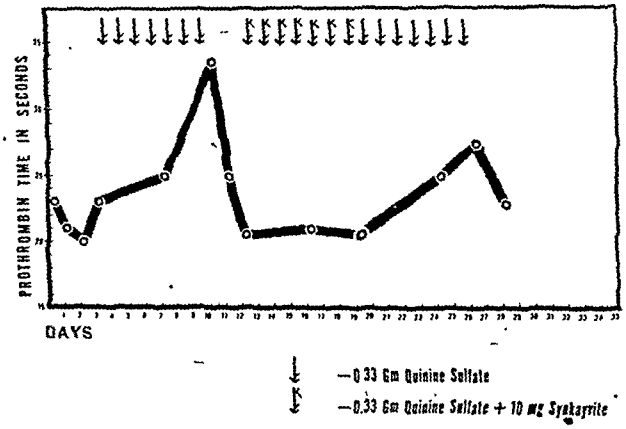

Chart 1.—Representative effects of quinine sulfate on prothrombin time and protective action of vitamin K in S. S., a white man aged 33. In this chart and in chart 2 it is shown that quinine sulfate produces prolongation of the prothrombin time; concurrent vitamin K administration counteracts quinine-induced prothrombinopenia; continuation of quinine sulfate without vitamin K causes another rise of the prothrombin time.

Quinine sulfate in single daily doses of 0.33 Gm. (5 grains) was administered by mouth for periods varying from six to sixteen days. One subject received 0.3 Gm. during the first phase of observation. In all subjects there was a significant rise of the prothrombin time, indicating a prothrombin lowering effect of quinine sulfate. The prolongations varied from 5 to 11.8

From the Pharyngology Research Laboratory (Harry Neivert, M.D., director), Columbia University College of Physicians and Surgeons, New York, and Hoffmann-LaRoche, Inc., Nutley, N. J.

Dr. Harry Neivert made it possible for the authors to conduct this work in his laboratory. Burroughs-Wellcome & Co., Inc., New York, provided the "Stypven" Russell Viper Venom used for the prothrombin estimations.

1. Page, R. C.; de Beer, E. J., and Orr, M. L.: Prothrombin Studies Using Russell Viper Venom: Relation of Clotting Time to Prothrombin Concentration in Human Plasma, J. Lab. & Clin. Med. **27**: 197 (Nov.) 1941.

seconds. On discontinuation of quinine sulfate the raised prothrombin times regressed promptly and approximated the respective control values within a few days.

Subsequently 4 of these subjects were placed on the combined oral medication of 0.33 Gm. of quinine sulfate and 10 mg. of a vitamin K compound daily, and this dosage was continued at least over the period of time in which quinine sulfate alone had produced a significant prolongation of the prothrombin time. The vitamin K compound used in this study was 2-methyl-1,4-naphthohydroquinone-diphosphoric acid ester tetrasodium salt, Synkayvite "Roche." The concurrent administration of vitamin K afforded full protection in all subjects against quinine-induced prothrombinopenia. The dose of vitamin K was an arbitrary one. The minimal amount required to render ineffectual the hypoprothrombinemic action of a given quantity of quinine remains to be determined.

In 2 subjects the combined quinine sulfate-vitamin K medication was followed immediately by a third experimental phase in which again a daily dose of 0.33 Gm. of quinine sulfate alone was given over a period of seven and eight days respectively. Both subjects promptly exhibited another pronounced elevation of the prothrombin time. The accompanying charts portray the experimental procedure, the dosages employed and the results obtained.

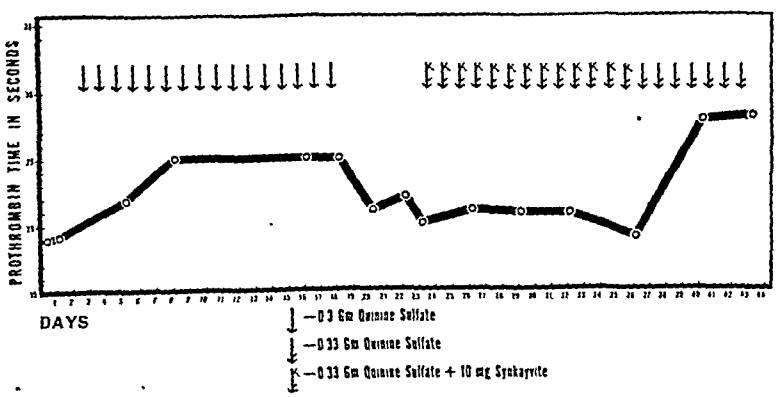

Chart 2.—Representative effects of quinine sulfate on prothrombin time and protective action of vitamin K in M. G., a white man aged 38.

Quinine hydrochloride was employed in two experiments not referred to before instead of quinine sulfate, which was used in the experiments described in this report. The hydrochloride salt also has an unquestionable hypoprothrombinemic action.

The evaluation of the significance of the findings reported awaits further study. While "there are no fixed levels of prothrombinopenia at which bleeding is known to be established" (Shapiro [2]), serious consideration must be given to the thought that prolonged administration of quinine, particularly if larger doses are employed, will interfere with normal blood coagulation. Neivert [3] recently demonstrated that acetylsalicylic acid induced hypoprothrombinemia is one of the most important etiologic factors of late tonsillar hemorrhage. He cautions that where there is wound healing by second intention a hypoprothrombinemic state should be avoided.

According to Sollmann [4] quinine still outranks all other drugs for the routine suppressive and curative treatment of malaria, in view of its effectiveness and low toxicity. Also for mass treatment without adequate medical supervision quinine therapy is most suitable. Strong [5] states that "in certain rural districts the free distribution of quinine has been almost the only important antimalarial measure that it was practicable to conduct."

With the world's most productive cinchona plantations in enemy hands, allied armies fighting in malarious regions are largely dependent on atabrine. For instance, Russell [6] of the Tropic Disease Control Section, Office of the Surgeon General of the U. S. Army, states that "under present conditions quinine prophylaxis is to be used only for men who cannot tolerate atabrine." At any rate the prothrombin blood level of those soldiers, sailors and marines fighting in malaria infested areas who do receive preventive treatment with quinine will be subnormal. If these men are wounded, normal blood coagulability will be impaired, resulting in prolonged bleeding. Later on, oozing from the wounds may occur, particularly if quinine medication is continued. Concurrent vitamin K administration is shown to counteract quinine induced prothrombinopenia. Consequently the combined medication would eliminate the danger of undue bleeding in these subjects.

Also all those malaria patients who, for corrective treatment, receive large doses of quinine for a long time may appropriately be given vitamin K regardless of whether or not there is any likelihood of being wounded. Manson-Bahr,[7] discussing the hemorrhagic forms of malaria, mentions that "hemorrhages may occur in almost any organ." Since quinine because of its prothrombinopenic effect—a property which, preliminary results indicate, is also exhibited by quinidine—is likely to increase the tendency to hemorrhage occasionally present in malaria, the combined administration of quinine and vitamin K will reduce the danger of hemorrhagic manifestations in these patients.

The relation of the present findings to the prothrombinopenic action of the salicylates is of interest. The action of the latter is firmly established [8] and the protective effect of vitamin K against such hypoprothrombinemia has been demonstrated.[9] It is worthy of note that quinine and the salicylates, which have entirely different constitutions, display a certain similarity with regard to their antipyretic action. But this does not

extend to the antimalarial effect which is peculiar to quinine. The prothrombinopenic action of the two drugs presumably is not related to their main or therapeutically desirable actions, and it is therefore surprising that quinine affects the prothrombin level the same way as do the salicylates.

SUMMARY

Quinine sulfate induces hypoprothrombinemia which can be prevented by concurrent administration of vitamin K. The concurrent administration of vitamin K to combat troops receiving quinine has been suggested for the purpose of eliminating the danger of prolonged, prothrombinopenia-induced bleeding from wounds. The routine administration of vitamin K in conjunction with quinine given for curative treatment is also proposed.

Clinical Notes, Suggestions and New Instruments

NASAL CONGESTION FROM FREQUENT USE OF PRIVINE HYDROCHLORIDE

SAMUEL M. FEINBERG, M.D., AND SIDNEY FRIEDLAENDER, M.D.
CHICAGO

Our first clinical experience with privine hydrochloride intranasally in allergic and infectious rhinitis gave us the impression that it was the most effective vasoconstrictor available. The continued use of this drug in our practice, however, began to give us increasing evidence that in addition to its vasoconstrictor action there was a congestive phase. In the last year or so we have been impressed with the large number of patients in whom symptoms of nasal congestion have been aggravated or prolonged by the continued use of privine.

We have seen at least 75 patients, with additional numbers being added every week, whose nasal congestion has been aggravated or maintained by privine. The usual course of events is as follows: The patient having hay fever or perennial allergic rhinitis begins to use privine for relief. Occasionally this start of the continued use of the drug may have its origin in the attempt to relieve the symptoms of a common cold. The medication may have been obtained without order from a physician, usually is prescribed by a physician but refilled without his knowledge, and in some instances was prescribed by us as long as one or two years ago. The patient notices that his nasal congestion is becoming increasingly pronounced, obstruction more complete and lasting and the immediate effect from the drops shorter in duration. Finally the turgescence becomes so severe that he finds it necessary to instil drops every hour or two, even during the night. In the vast majority of instances the privine still continues to show some vasoconstrictor action, so that the sufferer, observing this temporary benefit, does not realize that the same drug is responsible for the increasing congestion of his nasal tissues. Intranasal inspection shows considerable turgescence of the inferior turbinates, giving the typical appearance of vasomotor rhinitis. Smears of the nasal secretion almost always show eosinophils. The exact interpretation of these findings is still open to debate, however, since practically all such cases that we had the opportunity to observe were those of allergic rhinitis in which the condition was aggravated by the use of privine. What the findings would be in persons under similar circumstances is something we hope to be able to report in the future.

In essentially all instances the discontinuance of privine results in much improvement in a week or less. Some patients are reluctant to discontinue what they feel is the only source of relief available. During the first two or three days after the drops are discontinued the nasal obstruction may be severe. During this period it may be advisable to prescribe a sedative to aid sleep; we have used either seconal or pentobarbital sodium. Ephedrine orally may be of some aid, and in occasional cases one may have to allow the sparing use of 1 per cent isotonic solutions of ephedrine sulfate.

Privine hydrochloride is marketed in 0.05 per cent and 0.10 per cent solution, the former being recommended "for children or patients with an extremely sensitive nasal mucosa." Chemically it is 2-naphthyl-methyl-imidazoline hydrochloride, a colorless substance readily soluble in water or saline solution. The marketed solution is isotonic and has a p_H of 6.2, approximating that of the normal nasal secretion. The action of privine, as of other sympathomimetic drugs, is by constriction of the peripheral vascular bed through stimulation of the sympathetic nerve endings. Prolonged action, isotonicity and compatibility with ciliary action are features stressed by the manufacturers. Its vasoconstricting effect is produced rapidly, lasts from two to six hours (in the beginning of its use) and is free of any tingling, burning or smarting.

The congestive effect from continued use of privine might be attributable to one or more possible actions of the drug: 1. It could be assumed that this substance has a vasodilator component in addition to its vasoconstrictor action. 2. The increased vasomotor changes might be due to an allergy to the drug induced by repeated use. 3. The irritability of the tissue could be explained on the basis of chemical irritation or injury if the drug was a primary irritant. 4. The vasodilatation could be due to a simple reaction following an intense and prolonged vasoconstriction.

Epinephrine possesses both a vasoconstrictor and a vasodilator element, referred to as sympathin E and sympathin I, respectively. While the vasodilator effect is weaker, it has a more prolonged action than the vasoconstrictor component. Thus when the vasoconstrictor effect has ceased the dilator factor still operates. Evidence of the presence of these two factors may be found in the so-called "epinephrine reversal," in which ergotoxine or yohimbine is used to paralyze the receptor mechanism in smooth muscle which ordinarily responds to the excitatory action of epinephrine. The administration of epinephrine in yohimbine or ergotoxine treated animals results in immediate vasodilatation without preceding vasoconstriction. For this reason, and probably also because of the dilatation secondary to intense vasoconstriction, epinephrine has been found unsuitable for routine intranasal application. According to Goodman and Gilman,[1] neither ephedrine nor amphetamine (benzedrine) possesses this vasodilator factor. Craver, Chase and Yonkman[2] demonstrated recently that blood pressure reversal was never obtained with privine in yohimbine treated animals. It is interesting to note also that these workers showed that cocaine, unlike its action in combination with epinephrine, does not have any potentiating effect on privine.

It has been inferred by some that the secondary congestive action of privine is due to an allergy induced by the continued local use of the drug. Support for such an explanation of the dilator mechanism lacks good evidence. Other sympathomimetic drugs have shown allergic responses very rarely. Scratch tests with 0.1 per cent privine solution on a number of persons having the typical congestive effect from this drug have been entirely negative. No other manifestations of allergy, such as dermatitis of the skin of the upper lip, asthma or urticaria have ever been noted by us in any users of this drug. It is true that in almost all instances we have found eosinophils in the nasal smear; however, it should be remembered that in our practice we were dealing almost exclusively with patients who were primarily allergic.

Nasal congestion depending on a primary chemical irritation is not a satisfactory explanation of the behavior of privine. This solution is isotonic, has a p_H physiologically compatible with the nasal secretions and is singularly free from smarting, burning or other evidence of primary irritation.

From the Department of Medicine, Division of Allergy, Northwestern University Medical School.

2. Craver, B. N.; Chase, H. F., and Yonkman, F. F.: Pharmacologic Studies of a New Vasoconstrictor 2-Naphthyl (1') Methyl Imidazoline Hydrochloride (Privine or Naphthazoline): II. Vascular and Respiratory Reactions in the Anesthetized Dog, J. Pharmacol. & Exper. Therap. 82: 275 (Nov.) 1944.

Vasodilatation as a reaction of intense vasoconstriction is the most plausible mechanism of the action of privine. Increased vasodilatation after constriction is a common phenomenon in exposure to cold, fright and other stimuli. It is to be expected that the degree of such vasodilatation would be dependent on the intensity and duration of the vasoconstrictor action. The relative pressor potency of privine is from one fifth to one third that of epinephrine, while its duration of action is two to three times that of the latter.

A number of other reports have been made dealing with the congestive effect of nasal vasoconstrictors, some of these including or singling out privine. In 1934 Scarano[3] studied the secondary reactions (returgescence, atony and bogginess) following a weekly period of three times daily nasal instillation of ephedrine or amphetamine in oil. Varying degrees of secondary reactions were noted in 5 of 25 cases with ephedrine, while reactions from amphetamine were virtually negligible. During a period of six years Sternberg[4] observed and followed up 32 patients whose nasal discharge and obstruction were more responsible to the continued use of vasoconstrictors than to the underlying allergic condition A total of eleven different vasoconstrictors was used and the authors observed no evidence as to which one produced most of the damage. Sprays were found to be less harmful than drops. Kully[5] likewise is of the opinion that not one of the sympathomimetic drugs is free from the secondary congestive effect. He states that the degree of congestion is proportionate to the intensity of the vasoconstrictor action and the frequency and duration of its use. He makes the emphatic statement that in many years of observation he has not encountered a single patient who used any of the vasoconstrictors to excess and remained free from the typical after-congestion.

Gollom[6] reported 30 cases in which nasal obstruction was prolonged by the use of privine. The typical histories of his cases are very much like ours, except that apparently in most of his cases the protracted use of the drug followed the attempted relief of a cold Schiller,[7] in a note to the editor of the *New England Journal of Medicine*, has called attention to the prolonged congestive effect of privine when used in seasonal hay fever. The author states that he has never seen such reactions and addiction following the use of ephedrine or other constrictors He believes that privine should not be used for a longer time than four or five days

Even prior to the foregoing reports on privine, in the book one of us[8] published in April 1944 the following statement was made: "We have noted that not infrequently the prolonged use of this drug (privine) establishes a reflex 'rebound,' i. e, an increased congestion after the effect of a single topical application has subsided" This preliminary note, written almost two years ago, has been amplified many times in our subsequent experience. As a matter of fact, the vasomotor rhinitis ensuing from the prolonged use of privine has become one of our most common medical problems in our office practice. The definite amelioration of this troublesome congestion following the discontinuance of the drops has been one of the most dramatic experiences we have witnessed.

SUMMARY

1. Privine hydrochloride, used in nose drops, commonly results in a rebound congestion of the mucosa. This action is due primarily to the vasomotor dilatation as a reaction from the intense vasoconstriction.

2. Other nasal vasoconstrictors may perhaps also produce similar effects, but to a less striking degree. In our practice, however, congestion from the continued use of other constrictors has been noted rarely.

3. The discontinuance of all nasal medication usually results in the alleviation of congestion in a week or less.

4. It is recommended that the use of privine in commonly used concentrations be discouraged in all cases in which prolonged nasal medication is desired. It is possible that further experimentation may indicate that weaker solutions may be better tolerated.

THE TREATMENT OF IMPETIGO CONTAGIOSA WITH SULFATHIAZOLE IN AN ALCOHOLIC PLASTIC VEHICLE

CAPTAIN R. H. DRAEGER (MC), U S N, AND
LIEUTENANT MICHEL PIJOAN (MC), U S.N.R.

The treatment of impetigo contagiosa has always been an acute problem particularly in children, owing to the extreme contagiousness of the disease. This disease has been reported among war refugees[1] and has recently assumed military importance.[2]

The etiology of impetigo is somewhat obscure and there is no uniform agreement regarding the agent responsible for the disease. Some[3] regard the streptococcus as the etiologic agent, others[4] believe a virus responsible, but the more general opinion[5] is that staphylococci, so prevalent in the lesions, are responsible for the disease In spite of the fact that reinfection is common among children, one of us (Pijoan) was unable to infect himself with material from impetiginous lesions in various stages of development.

The methods of treating impetigo have been extensive. To the lesions have been applied tinctures of mercurial disinfectants, copper sulfate-zinc,[6] solutions of ferric chloride,[7] boric acid-zinc ointment,[8] staphylococcus toxoid,[9] silver nitrate cautery[10] and the mechanical effect of adhesive plasters[11] There are also numerous reports dealing with the classic treatment with ammoniated mercury. The successful employment of these chemotherapeutic agents requires the use of surgical dressings. These dressings are difficult to apply especially to such anatomic areas as the ear, nose, mouth and eyelid They require a great amount of time and often become soiled, moist and loosened.

The use of sulfonamides in the treatment of impetigo has assumed prominence in the last few years. Effective therapy has been accomplished by oral administration[12] and topical application in ointments,[13] powders and microcrystals.[14] More uniform results have been obtained with sulfonamides than with other agents, and these appear to be the drugs of choice for the treatment of impetigo.

Mr. F V Worman secured patients for this study

Sulfonamides have also been successfully used in the treatment of impetigo,[15] without the use of dressings, by incorporating them in an aqueous plastic vehicle consisting of dimethoxy cellulose or polyvinyl alcohol. These preparations when topically applied dry slowly, leaving a transparent water soluble film through which the lesion may be readily seen. The presence of exudate seems to liberate the drug from the water soluble plastic. While these films are therapeutically effective, the chief disadvantage is their slow drying time from ten to fifteen minutes.[16] The patients, usually children, often become restless and disturb the drying film. This disadvantage has been overcome by the addition of 70 per cent alcohol to the vehicle, which results in a much shorter drying time. While dimethoxy cellulose and polyvinyl alcohol are probably not completely soluble in 70 per cent alcohol, a satisfactory stable dispersion can be obtained by use of the proper technic.

PREPARATION OF SULFATHIAZOLE PLASTIC JELLY

The alcoholic plastic vehicle was prepared by adding dimethoxy cellulose (Dow-Methocel 15 cps.) or polyvinyl alcohol (Du Pont PVA-RH623 low viscosity) to 70 per cent alcohol containing the dissolved sulfathiazole in the proportions given in the following formulas. The preparations are thoroughly mixed in a Waring blendor and allowed to stand for about twelve hours to secure a homogeneous dispersion of the plastic. The methocel mixture is best kept in the refrigerator at + 5 C. during this period, while the polyvinyl alcohol may be slightly heated.

The addition of a small amount of plasticizers to the vehicle is necessary to secure a flexible film which will adhere properly to the skin. Triethanolamine and carbowax and glycerin are used in the formulas given. These preparations have a jelly-like consistency and are best dispensed from a collapsible metal tube.

The addition of 70 per cent alcohol to polyvinyl alcohol (RH-623) or dimethoxy cellulose (cps. 15) shortens the time required for drying as well as to increase the viscosities of these solutions.

The use of 70 per cent ethyl alcohol as a solvent for the preparation of the jellies yields products which are satisfactory in regard to their physical properties. The increase in viscosity results in a more viscous jelly as compared to preparations in which water is used as a solvent. Furthermore, a current of air from a fan hastens drying considerably; environmental conditions modify the drying of any substance which depends on evaporation for a result. Excellent adhesiveness is achieved with the plasticizers used, and it is to be supposed that other agents besides sulfathiazole can be incorporated in these jellies. The dry material or film is still water soluble and will dissolve in the presence of exudate and thus liberate a chemotherapeutic agent. When such jellies are spread on skin rather than on lesions they tend to dissolve in sweat, and reapplication may be necessary.

TABLE 1.—*Comparison of Viscosities and Drying Time of Cellulose and Polyvinyl Alcohol and Water Solutions*

	Ingredients as Gm. or Cc. for Preparation of Jelly

METHOD OF APPLICATION

The impetiginous lesion and surrounding area are soaked with hydrogen peroxide applied with a cotton pledget. Several applications may be necessary to loosen the crusts, which are removed by gentle débridement. Rough handling should be avoided, since it will result in increased scar formation. The lesion and surrounding area should be wiped free from excess peroxide and allowed to dry for several minutes. The sulfathiazole jelly is applied in a thin even layer and allowed to dry. One application may be sufficient; however, if further treatment is necessary the jelly may be reapplied without the use of hydrogen peroxide or débridement.

TABLE 2.—*Comparison of Therapeutic Results in the Treatment of Impetigo Lesions*

	Location of Lesions					
	Ear	Nose	Circumoral	Scalp	Extremities	Trunk
Number of lesions.....	26	18	30	16	36	15
Sulfathiazole in alcoholic dimethoxy cellulose jelly:						
Number of applications.....	3	1	1	1	1	1

Number of applications.....	7	13	11	15	5	11
Healing time (days).....	7	8	8	14	7	10

RESULTS

Through the courtesy of F. V. Worman, B.S., M.S.,[17] a bacteriologist collaborating with Dr. E. S. Stong,[17] 54 children with numerous impetiginous lesions were used for study. Approximately the same number of lesions were treated with each of five different preparations.

The therapeutic agents used were the two sulfathiazole plastic jellies, formulas 1 and 2, 3 per cent ammoniated mercury ointment, 3 per cent tincture of gentian violet and 5 per cent sulfathiazole ointment. Bandages were not used with any of the preparations. No difference was noted in the effectiveness of the two sulfathiazole formulas 1 and 2. A comparison of the results obtained with these preparations is shown in table 2.

The therapeutic results obtained by using sulfathiazole plastic jellies varied according to the location of the lesions. The shortest average period required for healing was two days and the longest was six days. The minimum time required to obtain healing with the other therapeutic agents was five days and the longest twenty-six days. In comparing the sulfathiazole jellies with other therapeutic agents without the use of dressings, it should be pointed out that somewhat better results would have been obtained with the other agents had dressings been used.

COMMENT

The topical application of sulfathiazole in an alcoholic plastic vehicle has the distinct advantage of drying rapidly and not requiring a bandage to retain the therapeutic agent in contact with the lesion.

17. Adams State Teachers College, Alamosa, Colo.

The effectiveness of sulfathiazole in plastic jelly in the treatment of impetigo appears to be due to limiting the spread of infection by the plastic film and the bacteriologic effect of sulfathiazole. The presence of exudate liberates the sulfathiazole from the water soluble film at the proper site.

CONCLUSION

Sulfathiazole in an alcoholic plastic jelly is highly effective in the treatment of impetigo contagiosa. The sulfathiazole jelly may be quickly applied, dries rapidly, is soluble in exudate and obviates the necessity for bandaging the lesions.

SUICIDE BY INGESTION OF AMPHETAMINE SULFATE

MAJOR O. L. GERICKE
MEDICAL CORPS, ARMY OF THE UNITED STATES

Death by taking an overdose of amphetamine sulfate is sufficiently rare to warrant reporting such an occurrence. Hertzog, Karlstrom and Bechtel,[1] state that the only fatal case they were able to find reported in the literature was that of Smith[2] in 1939, and they go on to present the case of a 1 year old child who accidentally consumed a minimum of four tablets, or 40 mg., of the drug with fatal outcome.

The comprehensive review of the pharmacology of amphetamine sulfate by Ivy and Krasno[3] cites the case of a student who died a few hours after taking a 10 mg. dose, and the cause of his death remained conjectural in spite of an autopsy.

The present case with death following the deliberate consumption of an estimated 120 mg. of amphetamine sulfate points to the fact that the substance is a therapeutic aid with dangerous potentialities and that the indications for its use should be carefully evaluated before it is prescribed in heroic dosages for narcolepsy, torticollis and other neuropsychiatric conditions.

REPORT OF CASE

A white man aged 36, American, a soldier, was referred for neuropsychiatric consultation by the psychologist during routine screening of absentees because of the unusual finding of his score of 150 on the Wechsler Intelligence Test—in spite of only eight years of schooling and a history of alcoholic spree drinking. The subject related that his childhood was unhappy because his parents were strict devotees of a religious faith which forbade their children modern pleasures, such as attendance at moving pictures, and maintained discipline through the liberal application of corporal punishment. One of the subject's most vivid childhood recollections was of his parents' customary evening journey to religious services, after impressing on the children their firm belief that the end of the world might come in their absence. The children remained fraught with fear during the parents' nocturnal devotions. The patient left this uncongenial home at the earliest opportunity and obtained employment at the age of 16 at a race track in Tijuana, where part of his daily routine for a three month period consisted in the consumption of a quart of whisky. He subsequently did laboring work, served one enlistment in the Regular Army and was a salesman, filling-station operator and fisherman, operating his own boat. In the meantime he married, had a son, was divorced, remarried, and at the time of his interview had also a paramour and an illegitimate child. By now the patient had gained a superficial insight into his personality and recognized the fact that he had periods when he felt "blue" and could gain surcease from his dysphoria by drinking himself into a week-long stupor. Isolation from other people by a solitary fishing expedition was equally efficacious and a much more profitable cure for the "blues." Ultimately, the mutual and sympathetic understanding of his paramour proved able to tide him over his moody spells.

Because of the man's intelligence and interest in his own problem he was given frequent interviews, and therapeutic reading was prescribed, as well as amphetamine sulfate to mitigate his enforced abstinence and avowed feeling of depression. Physical examination was within normal limits, and there was no evidence of psychomotor retardation or depressed facies.

On April 18, 1945 the patient was seen briefly, and he stated that he had had no difficulty in sleeping the previous night, but he complained of loss of appetite. He was given specific directions to take only 5 mg. of amphetamine in the morning and to continue with that dosage until his supply of drug was exhausted.

About 10 p. m. April 18 the soldier attracted the attention of one of his noncommissioned officers and told him he felt ill, whereupon he was transferred to the hospital for admission. A search of his possessions revealed the following letter addressed to the psychiatric social worker, given here as written:[4]

Dear Mr.————,

Ive just made a decision that will seem to you a very weak way of solving this blue-spell, and don't even find reason to really justify it myself but at least you'll not be bothered with having to listen to my crazy explanations that dont even make sense to me.

I've already taken 4 of the pills and Im going to take the rest sometime before morning, I know its going to spoil the Majors experiment by taking these pills this way, but they weren't doing any good the other way. I'll be over *this* blue-spell any way I just cant sweat it out any longer, honestly I did try in every way and tried to co-operate with you and the Major in finding the cause, but its no use I just cant think straight even when I try to tell either of you how I feel and I just feel like a damn fool instead. Thanks any way for all you did, and maybe I did help you in at least understanding a little bit more about the next case you have like mine.

The following running comment was also found and apparently terminated at the time he began to feel so ill that he called for aid:

Its been about 20 min since I took the first 4, dont feel nothing yet but just got through taking 8 more maybe I'll get that elated feeling one more time at least, if a dozen dont do it Ill keep taking them 4 at a time till they do. If I live through this, I'll at least know how it feels to come from the depths to the hieghts. its made me belch twice that all, well of all the places to feel a sensation my right foot feels like its getting numb. my heart is pounding and I feel a pulse in my head that seems to start from behind and go around counter clock-wise and stop about even with my left ear. I sure as hell dont feel any elation though only a determination to carry this through and stop these blues once and for all. If they know very little about them with all their knowledge how the hell can I ever know whats causing it. Its funny but I dont feel sorry for myself or that Im a martyr about this. I always figured that people who took this way out were weak and yet I dont feel that way about myself, must be ego I guess. Ive no new feelings so Im going to take 4 more. my temples are pounding now and it feels like my legs were away off

The soldier was admitted at 10:15 p. m. and the admitting officer noted that he was in a dazed condition. His pulse rate was 58, strong and full. The pupils reacted to light and in accommodation and he complained of an intense headache, frontal in type. A mannerism of continually sweeping the left hand over the forehead and left eye was present. The nurse's notes give the additional information that the patient appeared wide awake on entry but seemed very nervous. At 11:30 the nurse noted that the patient's right leg and arm were paralyzed; he had difficulty with breathing and was involuntary. At 12:30 a. m. the pulse rate was 56; respiration was not labored, and the blood pressure was 140/80. Questions were answered with difficulty. The right leg and arm appeared paralyzed; however, reflexes were present. His condition remained the same, the pulse becoming somewhat stronger, and at 2:30 the pulse rate was 80, the color was good and respiration was not labored. His condition remained stationary until 4 o'clock, when an attack of vomiting occurred. The vomitus consisted of a brownish fluid. At 4:05 the rectal temperature was 103.8 F. Caffeine and sodium benzoate and administration of oxygen failed to bring about any improvement in his condition. The respirations were labored, the pulse was over 100 and the patient's condition became steadily worse until he died, at 4:55 a. m. on April 19.

Autopsy showed no gross findings of interest until the cranial vault was removed and the dura exposed, when the autopsy surgeon noted that the cerebral hemispheres showed a flattening of the convolutions, and there was a dark hemorrhagic

4. Such errors in grammar and spelling as are found in the letter had not appeared in the previous writing of the patient. Their appearance here may be ascribed to his physiologic state.

area approximately 4 cm. wide extending from the right temporal lobe upward and backward along the central fissure to the longitudinal fissure. A small cut section through this area revealed the hemorrhage to be about 1 cm. in depth, and it extended above the arachnoid space into the brain tissue. There was a blood clot approximately the size of a walnut in the cerebellopontine angle. The entire brain was removed for further section. The brain tissue was so extremely soft and friable that it could not be preserved intact.

The pathologist, on examination of tissue submitted to him, noted a mass of clotted blood measuring 7 by 4.5 by 2.5 cm. beneath the dura on the right side. Over the right cerebral hemisphere there was considerable subarachnoid hemorrhage involving the parietal and anterior portion of the occipital lobes. There were no areas of contusion involving the brain substance. Considerable congestion throughout the white matter of the cerebral hemispheres was observed, and several tiny petechiae were present. There were multiple small hemorrhages of the pons. The cerebellum showed a few tiny "ring" hemorrhages. The final diagnosis was:

Cardiovascular: Coronary arteriosclerosis.

Respiratory: Pulmonary congestion and edema. Pulmonary emphysema.

Spleen: Congestion of spleen.

Genitourinary: Congestion and hemorrhages of kidney.

General nervous system: Subdural and subarachnoid hemorrhage, right parietal and occipital lobes. Petechial hemorrhages of cerebrum and cerebellum. Hemorrhage of pons.

An analysis of the stomach contents was negative for amphetamine sulfate.

SUMMARY

Death of a 36 year old man followed the ingestion of an estimated 120 mg. of amphetamine sulfate taken with suicidal intent. The immediate cause of death was subdural and subarachnoid hemorrhage of the parietal and occipital lobes.

Council on Industrial Health

MASS HEALTH SURVEYS IN INDUSTRY

This statement has been prepared by the Council on Industrial Health and approved for publication.

C. M. PETERSON, M.D., *Secretary.*

An important component of industrial health examinations is the discovery of nonoccupational disease, often in incipient and readily manageable stages. Early detection of illness and prompt adequate treatment are in the best interests of the worker, the employer, the community and the medical profession.

Increasingly in recent years official and voluntary health agencies have regarded industry as a convenient avenue for special case-finding campaigns—especially tuberculosis, syphilis and defective vision. All have important relations to the general public health or are designed to improve production and earning power or to reduce troublesome absenteeism and wastage.

The Council on Industrial Health believes that these case-finding campaigns conducted in industry by outside agencies merit support and cooperation from the medical profession provided certain general principles are observed:

1. The local medical profession, health authorities and other affected community health facilities should be fully advised well in advance about the purposes and scope of the survey.

2. The personnel undertaking the survey must be professionally competent and employ acceptable equipment and procedure. Results of examinations should be interpreted by physicians of experience and training in the methods employed.

3. Mass health surveys are essentially screening operations. Unless preliminary agreement suggests otherwise, the details of confirmatory diagnosis should be regarded as responsibilities of the established medical, clinic or laboratory facilities in the community.

4. Full consideration needs to be given to the disposition of individuals with clinically significant findings. They should be promptly referred to personal physicians or other authorized community agency for additional study and individualized treatment.

5. Means for isolation, hospitalization or other essential treatment need careful evaluation in advance of the survey.

6. Reporting and epidemiologic investigation of communicable disease should conform with the regulations of the health department having jurisdiction.

7. Surveys should be conducted only after the plant medical service has had an opportunity to study the proposed activity and given its approval. The details of case finding should conform to accepted industrial health procedure and be integrated with the regular activities of the plant medical department. The industrial physician should be consulted particularly (*a*) on discovery of coincidental disease or disability having suspected occupational etiology, (*b*) regarding plans for referral of patients and follow-up and (*c*) about the details of reemployment, especially placement in suitable occupations of individuals with residual impairment.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

HEXAVITAMIN TABLETS.—"Hexavitamin Tablets contain in each tablet not less than 2,500 U. S. P. units of vitamin A from natural (animal) sources, 200 U. S. P. units of vitamin D from natural (animal) sources, or as activated ergosterol or activated 7-dehydrocholesterol 37 mg. of ascorbic acid, 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin and 10 mg. of nicotinamide."—U. S. P.

For description and standards see the U. S. Pharmacopeia XII First Bound Supplement under Tabellae Hexavitaminarum.

Actions, Uses and Dosage.—For prophylaxis and treatment of conditions arising from deficiency of vitamins A and D and ascorbic acid, thiamine, riboflavin and nicotinic acid. See articles on the various vitamins concerned (N. N. R. 1944, pp. 604-625).

INTERNATIONAL VITAMIN CORPORATION, NEW YORK

Tablets Hexavitamin: Each tablet contains 2,500 U. S. P. units of vitamin A, 200 U. S. P. units of vitamin D, 37 mg. of ascorbic acid, 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin and 10 mg. of niacin amide.

NICOTINAMIDE (See New and Nonofficial Remedies 1944, p. 617).

The following additional dosage form has been accepted:

GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Tablets Nicotinamide: 100 mg.

TRIASYN B.—"Triasyn B Capsules and Tablets contain in each capsule or tablet not less than 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin and 10 mg. of nicotinamide."—U. S. P.

For description and standards see U. S. Pharmacopeia XII First Bound Supplement under Capsulae Triasyni B and Tabellae Triasyni B.

Actions, Uses and Dosage.—For prophylaxis and treatment of conditions arising from deficiency of thiamine, riboflavin and nicotinic acid. See articles on the various vitamins concerned (N. N. R. 1944, pp. 606-615).

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Tablets Triasyn B: Each tablet contains 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin and 10 mg. of nicotinic acid amide.

Capsules Triasyn B: Each capsule contains 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin and 10 mg. of nicotinic acid amide.

FEDERAL PROGRAMS TO PROMOTE SCIENTIFIC RESEARCH

Under the Organization Section in this issue of THE JOURNAL appears an analysis of legislation pending in the 79th Congress to implement the recommendations regarding research contained in the report recently submitted to President Truman by Dr. Vannevar Bush. In addition to the proposals analyzed in this article, several others have been introduced with a view to continuance in the postwar period of the coordinated and intensified research that did so much for the advancement of medical and other sciences during the war. For instance, one measure introduced by Mr. Thomas of Utah on July 26 is designed toward increasing interest in children while they are in secondary schools.

The number and diversity of the measures proposed are themselves an evidence of the difficulty of finding a formula for the purpose that will accomplish the desirable objectives without introducing factors harmful both to research and to our system of government. Surely every one concerned would wish to avoid bureaucratic domination of research, inhibition of investigations carried on under private initiative, in industry, in schools and colleges or even by individuals, and the spending of funds without any reasonable likelihood of adequate return. Practically all the measures propose to develop a national research foundation as an independent agency in the executive branch of the government, yet there is no obvious consensus as to the way in which such an agency should be established, the funds that should be granted to it, the technic of its operation, the choice of its personnel, the duration of its activities or the manner in which it would cooperate with existing governmental and private organizations. Senator Kilgore himself recognized these difficulties in his hope that joint hearings might be held so that the issues presented by these bills could be clarified.

While these measures propose to coordinate and intensify research in various scientific fields, they would seem to demand a certain amount of coordination within their own proposals. Among the objectives sought are the stimulation of research in physical sciences, medicine and the national defense. Obviously advancement of medical science is a contribution to the national defense, as are no doubt also advances in the physical sciences. Nevertheless discoveries related to bombing, chemical warfare, new weapons and new technics of defense, aviation and transportation are somewhat remote from the control of infectious diseases, the detection of viruses and the prevention and cure of epidemic diseases. Discoveries in physics, chemistry and related sciences are often promptly explored for such benefits as they will yield in the diagnosis, prevention and treatment of disease, yet these are quite certainly not as closely related to medicine as are anatomy, physiology, pathology, bacteriology and immunology. The advancement of research in the medical sciences is indissolubly associated with undergraduate and graduate medical education, the functions of the hospitals and the practice of medicine. Some of the proposals completely ignore these necessary relationships.

Most of the proposals request a managing board of limited numbers with subsidiary advisory boards in the fields that have been mentioned. Without specific allocation of funds or influence to these subsidiary fields, the pressure of public opinion rather than the immediate good to the public may be the determining factors in the allocation of such funds as are made available. One of the dangers inherent in federal assistance is the possibility of a type of federal control over research and the results of research that would prevent the dissemination of new information and inhibit rather than stimulate investigative activities. Moreover, bureaucratic direction may serve to monopolize personnel to the extent of depriving private industry, private educational and research institutions and other nongovernmental agencies of the opportunity to secure workers in a field in which the number of competent investigators is always less than the demand for them.

Already agitation is obvious in behalf of the social sciences, sociology, psychology, economics and similar fields of learning. Surely such sciences might also benefit by the type of aid that government can render, yet the possibilities even with the physical sciences and with medical science have not been explored. The establishment of a pattern for action by the government in stimulating science might well be developed by the experimental technics of science before application is made to every phase of human life and learning.

The considerations that are here merely suggested are only a few of hundreds of questions that have already arisen in the minds of all those concerned with these projects. The least that Congress could do, under the circumstances, would be to provide for extensive hearings under proper conditions with representation from many interests before a measure that would include what seemed to be the most desirable features of all the proposals could be compiled. Even this measure when finally developed should be again submitted to new hearings before definite action by the Congress would seem to be warranted. Such delay as would be required might seem unfortunate, particularly now when all the world recognizes the accomplishments of science during the war and when every one would wish to retain in the postwar world the advantages that have been gained by coordinated and intensified research. Nevertheless the harmful potentialities in these projects are sufficiently apparent to require at least enough time for careful consideration before definite action is taken.

THE MATERNAL AND CHILD WELFARE ACT OF 1945

Senator Pepper and nine other members of the Senate Committee on Education and Labor have introduced a bill (see Organization Section, page 1112, this issue) designed to extend the provisions of the Social Security Act by increasing materially the funds available for maternal and child health services, services for crippled children, child welfare services, and an increased personnel of the Children's Bureau necessary for administration. Included are suggestions for research and for education of personnel. This bill is perhaps the official opening of a campaign to make permanent some of the activities that prevail under the so-called EMIC program.

Early in the establishment of EMIC, THE JOURNAL predicted that the Children's Bureau would not be happy until permanence had been given to this tremendous expansion of its activities. As with much other legislation for social welfare, few would oppose the objectives sought, namely promotion of the physical and mental health of mothers during maternity and of their children, preventive health work and diagnostic services for children, school health services, the care of sick children and the correction of physical defects. The allotment of federal funds to the individual states is now a well established principle in our government. The public has a right to ask that need be established before funds are allocated. The wisdom of placing control in the Children's Bureau through insistence that plans must be approved by the chief of that bureau before funds can be granted is subject to doubt. The chief of the Children's Bureau is to formulate the policies after consultation with the state health officers and an advisory committee. Nothing in the act says that the advisory committee is to have any authority or that its advice need necessarily be followed. THE JOURNAL has previously criticized adversely the political technic which permits the chief of a government bureau to select his own advisory committee and then even to disregard the advice of the committee that he himself selects.

In submitting the bill, Senator Pepper offered some interesting estimates. Thus he said:

> Medical care and health supervision of children is costly in dollars. Reliable authorities estimate it comes to somewhere in the range of $25 to $40 a year for each child in the United States. With 40,000,000 children under 18 that represents a total of at least $1,000,000,000 for the country. A federal appropriation of $75,000,000 for maternal and child health and for crippled children for a year cannot go very far in meeting these all-over health needs of children.

Almost coincidentally with the offering of this proposal came an announcement in the press indicating that Secretary Schwellenbach of the Department of Labor desired to see the Children's Bureau removed from that department and possibly incorporated in a new department of the government to be devoted to health and welfare. Whether or not President Truman, in his apparent wish to consolidate government agencies, will suggest the establishment of a new department in the cabinet to include the Children's Bureau, that agency long since should have been integrated with the other health activities of the nation.

ARMY ROUTINE IN TREATMENT OF MALARIAL ATTACKS

Discharged soldiers who have had malaria may have clinical attacks many months after leaving the service. Most of these attacks will be due to vivax infections. Of 18,171 analyzed attacks occurring in the United States in soldiers infected while oversea, 98 per cent were due to Plasmodium vivax alone. The attacks are generally mild and respond quickly to adequate treatment. Among 32,292 admissions for malaria to army hospitals in the United States in 1944 two deaths were attributed to the disease.

Febrile illnesses in discharged soldiers who have served in malarious regions should raise the suspicion of malaria. Thick blood films should be examined for parasites in such cases. The possibility of malarial relapses in ex-soldiers who undergo surgical operations must be kept constantly in mind. While it may occasionally be necessary to treat patients without an accurate laboratory diagnosis, such practice is dangerous and should not become routine. Other diseases for

which specific therapy is essential, such as pneumonia or meningitis, may be overlooked, with tragic results.

In general, the Medical Department of the Army on the basis of a huge experience prefers to use atabrine in treating usual cases of malaria. The standard Army treatment consists of 1 Gm. in divided doses in the first twenty-four hours, followed by 0.1 Gm. three times a day for six days.

As an alternative to atabrine for patients who do not tolerate atabrine, quinine, when available for oral use, or totaquine, which is freely available, may be used. The dosage of both of these drugs, as used in the Army, consists of 1 Gm. three times a day for two days, followed by 0.6 Gm. for five days. In civilian practice it is believed that this dosage could with safety be reduced slightly, especially for relapses of vivax malaria. Clinical studies by the Army both in the United States and overseas show that, in the dosage given, totaquine U. S. P. gives results as satisfactory as those secured with quinine.[1]

Many helpful details with regard to diagnosis and treatment, including the management of complicated and severe cases requiring parenteral treatment, are given in a recently published War Department Technical Bulletin.[2]

Available treatment will not prevent relapses of vivax malaria. Investigations by the Medical Department have shown clearly that courses of treatment like those given for clinical attacks are useless between relapses. To avoid the occurrence of attacks in close succession the Medical Department recommends that treatment for attacks be continued with small doses of an antimalarial for a variable period, usually at least ninety days. Atabrine is usually employed. The continuation dosage, which should not be exceeded, is 0.1 Gm. a day. On this dosage relapses rarely occur. If quinine is used, the Army found 0.6 Gm. a day necessary in oversea practice. This is a troublesome amount of quinine to take continuously, but breakthroughs were fairly common overseas when smaller doses were taken. Further information on this aspect of the subject is provided in another Technical Bulletin, Med. 136, on the Avoidance of Relapses of Vivax Malaria by Use of Suppressive Medication.

Physicians should exercise care in the choice of an antimalarial drug. Individuals who are sensitive to atabrine or seriously intolerant of it should receive totaquine or, if available, quinine. Similarly, persons who are sensitive to totaquine or quinine should receive atabrine. It should be remembered that totaquine U. S. P. contains about 10 per cent quinine. Persons sensitive to both atabrine and the cinchona alkaloids are seen only rarely.

Current Comment

DISCHARGE OF MEDICAL OFFICERS

In this issue of THE JOURNAL appears the official statement of the Army Medical Department relative to the discharge of medical officers. The Connecticut State Medical Society late in July adopted a resolution which was sent to the Board of Trustees of the American Medical Association and presumably to the officers of other state medical societies, urging that the American Medical Association "press the reactivation of the Procurement and Assignment Service in a workable and liberal advisory authority concerning the separation of medical officers and restore to it the same responsibility it exercised during the period of recruitment of medical officers." The resolution urged further that the American Medical Association and its components should seek the interest of the Congress of the United States in providing a clear and productive separation policy for medical officers. . . ." The policy presented in this issue of THE JOURNAL is one on which the officials of the United States Army and of the Army Medical Department have been working for some time. Recently the Michigan State Medical Society took action similar to that of the Connecticut State Medical Society. The organization known as the Association of American Physicians and Surgeons, Inc., according to the press, has sent a resolution to numerous officials of the government. This resolution lists a number of rumors, most of which are without the slightest foundation in fact. The officials of the Association of American Physicians and Surgeons could have found out how completely unwarranted these statements were before giving them publication and thus promoting dissatisfaction and disintegration of morale without the accomplishment of any conceivable worthwhile objective. Meanwhile word comes from Washington that the War Department has assigned Col. William P. Holbrook to help the Military Affairs Committee of the Senate investigate charges of overstaffing of doctors in the Army. Colonel Holbrook is to assemble all pertinent statistics on medical personnel and to have them ready for the committee when Congress reconvenes on October 8.

HEALTH LEAGUE OF CANADA

A report of the twenty-fifth annual meeting of the Health League of Canada, with headquarters at Montreal, is sent out in anticipation of the league's twenty-sixth annual meeting, scheduled for September 1945.[1] The silver anniversary publication reflects public health progress in Canada. The league has five technical divisions, dealing with immunization, industrial health, venereal disease, nutrition and pasteurization of milk. These are considered the five major challenges to health in Canada. Under these various headings important

1. Report of the Twenty Fifth Annual Meeting of the Health League of Canada at Montreal, Nov. 23 24, 1944.

needs are stressed, such as medical examination before marriage and antepartum examinations. These objectives are being attacked by the usual methods in health education: pamphlets, films, posters and local meetings and letters. Under the heading of Immunization, the educational attack was on diphtheria, smallpox, whooping cough and, in some provinces, scarlet fever; 20,000 lines of sponsored advertising in forty Canadian newspapers featured this campaign. The industrial health division has functioned mainly through the distribution to industry of posters, pay envelop inserts and instructive booklets; conferences also have been held. Production of a nutrition calendar was a prominent activity. Little progress is reported toward pasteurization of milk; only the province of Ontario requires the pasteurization of all milk. The Health League of Canada represents in Canada many of the activities which are carried on in the United States by special independent agencies known as voluntary health agencies. In view of current agitation of the issue of consolidation or federation of voluntary health agencies in the United States, the functioning of the Health League of Canada for a quarter of a century should offer interesting examples. While nations differ, there are probably no two peoples more alike than those of Canada and the United States. The Health League of Canada has an official publication, *Health*, which is published quarterly and reaches a coast to coast audience "of well over thirteen thousand readers."

RADIO TRANSCRIPTIONS FOR HEALTH GROUPS

On page 1114 of this issue of THE JOURNAL the Bureau of Health Education announces the seventh series of electrically transcribed radio broadcasts for local use by medical societies or by local health or welfare groups with the approval of the local medical society. With the addition of these transcriptions, this important and growing service now represents a well rounded coverage of the field in health education. A series titled Medicine Serves America deals with medical progress. Live and Like It, a dramatized series, considers the everyday health problems, such as weight control, sleep, prompt medical care and superstitions. Before the Doctor Comes is a series of informal question and answer discussions with doctors about common symptoms occurring in the family, such as cough, rash, earache, bleeding and similar minor but perplexing problems which must be faced while doctors are scarce. There is a series of twelve programs called Dodging Contagious Diseases: this title is self explanatory. For local societies desiring to remain on the air through the summer, twelve transcriptions are available under the title Keep Cool, which deal with summer problems such as suntan, swimming, bugs, poison ivy and hay fever. Health problems of middle age are dealt with in a series of thirteen platters featuring interviews with thirty-three prominent public health experts. The health problems of middle age form the subject of the series More Life for You, in which twenty-four medical and surgical authorities are interviewed. These seven series, a total of eighty-eight broadcasts, will suffice to keep a medical society or other local group on the air weekly without interruption for almost two years. The diversification of subjects allows for scheduling with regard to seasonal timeliness. The diversity of approach, including interviews, round table and dramatization, will lend variety and interest to the local series. Further information may be had by addressing the Bureau of Health Education, 535 North Dearborn Street, Chicago 10.

NARCOTIC PRESCRIBING BY TELEPHONE

The United States Commissioner of Narcotics has called attention to the difficulty that has resulted throughout the country because of the frequency with which physicians telephone their narcotic prescriptions. This practice, he reports, has resulted in abuse and in illicit traffic, many pedlers and addicts using this means to obtain morphine. In at least one community the practice has resulted in a federal grand jury investigation. The report of this grand jury, after describing the facts developed during the investigation as disclosing "a rather shocking disregard of the law" and as reflecting a condition "intolerable and wholly unwarranted," continued:

> We do not wish to place ourselves in a position or attempt to determine when or under what manner or in what quantities a person may need narcotics for the alleviation of pain or suffering, but we feel that we are in position to say that the conditions above referred to are intolerable and wholly unwarranted and, if continued, can only result in an indictment wherever warranted. It has been stated in defense of this condition that the doctors are overworked and prescriptions by telephone are time savers. We are conscious of the overworked condition of most of our physicians, but we disagree with the contention that such practice is warranted in order to save time. It is a matter of obeying or violating the law.
>
> We are making this report at this time in the hope that these abuses, as well as any others not mentioned herein, may be speedily corrected. We propose to pursue this investigation further when next called and will then take such action as the facts and circumstances warrant at that time.

Under existing regulation, the furnishing of narcotics pursuant to telephone advice of physicians is prohibited, whether prescriptions covering such orders are subsequently received or not, except in an emergency. In such an emergency, a druggist may deliver narcotics through his employee or responsible agent pursuant to a telephone order only if the employee or agent is supplied with a properly prepared prescription before delivery is made and this prescription must be turned over to the druggist and filed by him as required by law. Physicians will aid materially in preventing the abuse referred to by the Commissioner of Narcotics if they restrict orders for narcotics by telephone strictly to actual emergency cases.

MEDICINE AND THE WAR

REDEPLOYMENT AND SEPARATION OF MEDICAL DEPARTMENT OFFICERS

NOTE.—*Following is the text of the official announcement released by the Office of the Surgeon General, U. S. Army, relative to the discharge of Medical Officers.*—ED.

V-E Day found the War Department with approximately 65 per cent of its Medical Corps officers overseas, the largest number in the European and Mediterranean theaters, the others principally in the Pacific. Some time prior to the announcement of V-E Day the War Department had completed its planning for redeployment, readjustment and discharge. This plan provided for discharges of enlisted personnel in relation to the declining requirements of a one front war, based on length of service, length of overseas service, combat activity, decorations and number of dependents. The composite score was known as the Adjusted Service Rating. The separation of officers was not tied down initially to a specific Adjusted Service Rating although the War Department desired that, within the limits of military necessity, substantially the same type of equitable, objective considerations should govern.

The War Department's pre-V-E Day planning also laid down the principles to govern the movement of personnel out of the European and Mediterranean theaters once victory was achieved. Military necessity, governed by consideration of transportation and the strategic requirements of the Pacific, scheduled the movement of a considerable number of troops directly from Europe to the Pacific. This was particularly true of service troops—the Engineers, Signal and, to a lesser degree, Medical Personnel—which were to prepare the way for the large inflow of divisions which would arrive in the Pacific after a short period of furlough and retraining in the United States.

Within the limits of military necessity, which govern here as in every other phase of redeployment and discharge policy, men with the lowest Adjusted Service Ratings were to go to the Pacific directly. Those with a large number of points were to go to the Pacific via the United States or were to remain in the United States as a strategic reserve until a final decision could be reached concerning the need for them during the remainder of the Japanese war. Men with a still larger number of points would remain in Europe as the Army of Occupation, while those with the highest points would be returned to the United States as surplus. It did not follow that the surplus group would necessarily be discharged, since it was possible—in fact, probable—that some of these men might have lower scores and therefore be less entitled to discharge than others who had returned from overseas at an earlier date or were now in the Pacific awaiting replacement before they could be returned. To permit the discharge of men with low scores because the war in Europe was over and they could be brought home, while men with substantially higher scores would be forced to continue fighting in the Pacific, was clearly inequitable. A responsible policy had to provide for sending replacements to the Pacific to permit the return of their high score personnel for discharge.

While V-E Day found the Medical Department with approximately 35 per cent of its Medical Corps strength in the United States, the same did not hold for other arms and services. All of the divisions were out of the country, and the same was true of the Signal Corps, Engineer and other service personnel. The Medical Department had considerably more of its personnel in the United States because of the fact that the definitive care which the battle wounded received is given them, not in overseas hospitals, but in the large general and convalescent hospitals in this country. Likewise there remain many hospitals in the United States which provided medical care for the Service and Air Force troops still in this country as well as for the inductees and trainees. These hospitals had to be manned, and it had not been feasible nor desirable during the relatively short European war to exchange personnel between the United States and Europe. Extreme exigencies in shipping had placed great difficulties on exchange with the Pacific.

In working out the over-all plans for redeployment, it was logical to envisage that most personnel adjustments would be made in Europe, with the divisions cleared for the Pacific on embarkation, permitting the pesonnel a thirty day leave in the United States and providing for them a short retraining period to prepare them for the differences in Pacific warfare. There was no room in this plan for adjusting personnel once the divisions returned to the United States, since there was no one left here for exchange purposes, except a few raw recruits.

The Medical Department picture was, however, markedly different. Cognizant of these differences the Surgeon General requested and received permission to exchange personnel in the units coming through the United States to the Pacific on the condition that the units would be able to perform their mission at the time they left this country.

Over-all planning of the Surgeon General went beyond this one step of restaffing units in the United States.

During the spring of 1945, when the European war was reaching its climax and the Pacific war was accelerating, the Surgeon General had stripped the United States of all personnel that could possibly be spared to provide the fighting fronts with the maximum number of medical personnel. However, as the war in Europe began to draw to a close every effort was made to bring back the battle wounded as rapidly as possible, so as to avoid the errors of World War I, when the wounded were forced to wait for many months because of shipping stringencies. Not only was care taken to avoid a repetition of this, but it was essential that many European and Mediterranean hospitals be cleared quickly so that they could meet the early dates set for direct movement to the Pacific. Early 1945 found the European Theater with more than 191,000 patients; by the end of June this figure was approximately 65,000. May and June saw the return to the United States of 98,000 patients, all but 24,000 of whom came from the European and Mediterranean theaters.

During the first half of 1945, when the maximum numbers of medical personnel were being sent overseas, the number of patients remaining in the general hospital system in the United States, which treats almost exclusively overseas casualties, increased from 133,000 to 240,000.

With personnel flowing out and patients flowing in, the Surgeon General had planned long before V-E Day to request the return of Medical Corps officers as soon as the fighting in Europe ceased. A substantial requisition was placed on the European theaters shortly after V-E Day, but the tremendous

personnel shift in the theater and the uncertainty regarding individual scores, which were not available until almost six weeks after V-E Day, made it difficult for the theater to return personnel as rapidly as desired. Such personnel has by this time returned or is en route.

Permission to restaff the units coming through the United States and the early return of personnel to assist in the operation of the hospitals in the United States constitute but two of the four phases of the Surgeon General's plan. Realizing that the units which had to go from the European and Mediterranean theaters directly to the Pacific had to be filled not only in number but also with the proper types of specialists so that they could perform their mission on arrival, and realizing further that the Mediterranean in particular would have to dip down into personnel which had two or more years' overseas service to find specialists to balance these units, the Surgeon General recommended exchanges between the European and Mediterranean theaters to avoid sending high score personnel to the Pacific. After some delays this policy was put into effect, but it will not completely obviate the unfortunate situation in which certain scarce specialists will have to proceed directly to the Pacific without passing through the United States because the exigencies of war permitted no delay in shipping dates.

The final point in the Surgeon General's plan was to prepare the groundwork for an accelerated exchange of personnel with the Pacific, as soon as part of the surplus personnel in the European and Mediterranean theaters was returned to the United States, so that replacements could be sent from the United States to the Pacific.

To implement the restaffing of units scheduled for the Pacific coming through the United States, a complete census was undertaken of all personnel stationed in the United States. On the basis of this census and in light of experience to date, criteria were established for withdrawing personnel from units passing through the United States and for assigning personnel now in the United States to the units scheduled for the Pacific.

These are only general rules and are subject to exception in any case due to military necessity, and to change if subsequent developments should make such action necessary. They are not to be understood as creating any right in an officer to continue on duty in this country if military needs now or later should require his assignment to other duty. Subject to these qualifications, the plan for withdrawal of officers from units and for new assignments is shown in the accompanying table.

The fact that more stringent criteria for withdrawal and assignment were established for Medical Corps officers than for other Medical Department Corps reflected smaller availabilities of Medical Corps officers than of other Medical Department Corps.

Because there is nothing in this plan of medical redeployment which takes precedence over considerations of military necessity, it will not be possible to apply the withdrawal principle to Commanding Officers and Executive Officers of hospital units or to certain Medical Department personnel attached to divisions because adequate replacements cannot be found and trained within the available time.

Moreover, there is nothing in the plan which stands in the way of volunteering. If an individual desires service in the Pacific, he can go if he passes the physical qualifications, irrespective of age, score or prior overseas experience.

Despite the above qualifications, it is hoped that the criteria outlined in the preceding table can be followed in the case of the vast majority of Medical Department officers returning through the United States for redeployment to the Pacific.

Intimately associated with the problem of redeployment are problems of readjustment and discharge. Reference has already been made to the fact that the original plan of the Surgeon General contemplated the sending of replacements to the Pacific at the earliest possible date, in order to permit the return to the United States of personnel who have had long overseas service. One phase of this plan is already in operation. Large numbers of nurses who have been in the tropics for two or more years will soon have the opportunity of returning to the United States while the theater will have the benefit of a group that has not yet suffered from the exhaustions incident to life in the tropics and to combat.

At first glance it might appear difficult to understand how it happens that several months after V-E Day, with the scale of combat having shrunk from a two to a one front war, the Army has only now begun to separate Medical Corps officers and other Medical Department personnel. The 98,000 patients who were brought back to the United States in May and in June were preceded in March and April by 89,000 patients, or a total of 187,000 patients during a four month period. On the basis of detailed experience tables for World War II, the average overseas casualty returned to the United States for definitive treatment remains in a hospital in this country for five to six months. This means that, although there have been only Pacific casualties since V-E Day, there were a sufficient number of casualties prior to V-E Day to keep the general and convalescent hospitals in this country operating at or near peak until late fall of this year. The Medical Department personnel that are attached to divisions in Europe and in the Mediterranean have, of course, not been busy with the care of casualties since V-E Day, although a considerable number were forced to assume the job of caring for the thousands of sick and wounded displaced persons in the areas overrun by the American armies. However, this "divisional" personnel has for the most part been busy dismantling forward hospitals and moving to the staging areas for embarkation either directly to the Pacific or through the United States. In addition, there are many thousands of Medical Department officers at the present moment on the high seas and many other thousands on leave in the United States preparatory to taking up assignments in this country, so that others who have not yet been overseas can go.

When hostilities ceased in Europe, the worldwide medical picture was this: an expanded war in the Pacific with vastly increased requirements, not only to cope with the engagements that were to be launched, but to facilitate the return to the United States of large numbers of personnel who have had long service in the Pacific for reassignment or separation. The United States had a peak patient load and would soon have thrust upon it a substantially increased medical processing load incident to the return of troops for redeployment to the Pacific or for discharge. This meant that the surplus brought about by a shrinkage from a two to a one front war was largely in Europe, where it could not be used for any of the strategic purposes for which it was needed: that is, to permit the separation of high score personnel, which could only take place

Plan for Withdrawal and Assignment of Officers

Corps	Age		A. S. R.		Overseas Service V-E Day (Months)	
	Withdrawal	Assignment	Withdrawal	Assignment	With-drawal	Assign-ment
Medical Corps	45 or over	44 or under	75 or over	74 or under	12	0
Dental Corps	40 or over	39 or under	50 or over	49 or under	6	0
Medical Administrative Corps	40 or over	39 or under	50 or over	49 or under	6	0
Sanitary Corps	40 or over	39 or under	50 or over	49 or under	6	0
Veterinary Corps	40 or over	39 or under	50 or over	49 or under	6	0
Army Nurse Corps	40 or over	39 or under	30 or over	29 or under	6	0
Physical Therapists Corps	40 or over	39 or under	30 or over	29 or under	6	0
Medical Department Dietitians	40 or over	39 or under	30 or over	29 or under	6	0

after such personnel had been returned to the United States, to take up assignments in the United States and help carry the peak load or to serve as replacements for individuals to be sent to the Pacific so that the latter could return its high score personnel to the United States for separation.

The keynote to the separation policy was therefore to give consideration to the participation of all theaters and to be certain that the surplus theaters—European and Mediterranean—would return their personnel at the earliest possible moment. At the end of World War I, with the war terminating for all at the same time, demobilization could be haphazard and yet substantially equitable: Off the gang plank and out. Such a procedure after V-E Day would have been unthinkable. There was a complication over and beyond the necessity of including the Pacific and providing for its participation in any separation plan. As was true of redeployment, military necessity had to govern and take precedence over any individual's score. The keynote to the efficient medical service in this war has been the careful marshaling of the limited number of key specialists who, despite every effort that has been made to utilize their skills to the full, have proved insufficient in number.

The separation plan of the Surgeon General had to deal, therefore, not only with numbers but also with classes of personnel. On the basis of detailed studies it was decided that it would be best to establish two classes—one for scarce specialists, the other for nonscarce specialists and general duty officers—and to set a definite score for each, so as to keep under strict control the outflow of scarce specialists. Consideration was given at one stage of the planning to prohibit the release of any officers in the scarce class, but it was believed better to plan where possible to release very high score individals as well as those over 50 years of age, irrespective of specialty, so long as the number of such releases would not endanger the efficiency of the medical service. The list of scarce specialists was kept to a minimum, after a review of worldwide requirements and availabilities.

Although readjustment regulations place responsibility on the Chief of each Technical Service for the establishment of separation policies, the Surgeon General felt it incumbent on him to establish a representative Separations Board and to charge this board with developing a series of objective criteria which would insure the continuation of high medical standards during the Pacific war and, at the same time, provide an equitable basis for the separation of surplus officers. The Deputy Surgeon General was designated Chairman of the Separations Board, and representatives of the three major forces—Army Air Forces, Army Ground Forces and Army Service Forces—were made members of the Board.

Establishment of Separations Board

The Board thoroughly explored all aspects of the separation policy and had at its disposal comprehensive statistical material before deciding the criteria for separation.

The Board decided to establish definite criteria for separation, subject, as above stated, to the limits of military necessity which governs all discharge policy. These criteria, therefore, create no vested right in any officer to discharge but constitute the goal to be sought, and the general rules to be applied in the absence of supervening military necessity. Such necessity may exist as to the time when, in any individual case, this step can be taken. Also it may arise from the possible need for a relatively few officers with irreplaceable experience whose usefulness is so great as to transcend individual consideration. Separations will be considered by the Surgeon General's Office and granted within the above principles wherever possible. The criteria hereafter set forth and all provisions of the present statement of separation policy must be read and understood as subject to the above qualifications.

Criteria for Separation from the Service

1. Medical Corps officers returned by a theater or declared surplus by a major force (except those with primary military occupational specialties listed in paragraph below) are eligible for release from active duty if their Adjusted Service Rating is 100 or above.

2. Medical Corps officers in certain scarce military occupational specialties are eligible for release from active military duty if they have an Adjusted Service Rating of 120 or more:

Gastroenterology	Neuropsychiatry
Ophthalmology and Otolaryngology	Neurosurgery
Cardiology	Thoracic Surgery
Dermatology	Plastic Surgery
Allergies	Orthopedic Surgery
Anesthesia	Clinical Laboratory

3. Medical Corps officers over 50 years of age, irrespective of their specialty classification, are eligible for relief from active military duty if they are returned to the United States by a theater or declared surplus by a major force.

4. No Medical Corps officer with an efficiency index of 41 or more who desires to remain on active military duty will be relieved, irrespective of age, military occupational specialty or Adjusted Service Rating.

Paragraph four is in keeping with the spirit of readjustment regulations which provide that individuals who desire to remain on active duty will be given every consideration.

Because of the fact that the general hospitals in the United States are now at peak and because the Surgeon General desires to send replacements to the Pacific as quickly as possible, the age provision is not being put into effect at the moment for personnel in the Army Service Forces, and *no Medical Corps officers in the nonscarce category is being released who has less than 110 points (except those who returned from overseas since V-E Day).* However, it is hoped that when more of the surplus personnel is returned from the European and the Mediterranean theaters, this temporary expedient can be lifted.

Subject to the general qualifications stated, the accompanying table summarizes the criteria for separation established for all Medical Department Corps.

Criteria for Separation

Corps	*Age*	*A. S. R.*
Medical Corps *	50 or over	100 or over
Dental Corps	45 or over	100 or over
Medical Administrative Corps	45 or over	90 or over
Sanitary Corps	45 or over	90 or over
Veterinary Corps	50 or over	110 or over
Army Nurse Corps †	40 or over	65 or over
Physical Therapists Corps †	50 or over	65 or over
Medical Dietitians Corps †	50 or over	65 or over

* Scarce categories, A. S. R. 120.

† The following additional provisions cover separations: dependent children under 14; married to demobilized allied personnel.

As in the case of Medical Corps officers, the Army Service Forces, for the time being, have not placed into effect the age provision for Dental Corps officers, and they are operating under a score of 110. But it is hoped that this exception can be removed later.

The foregoing criteria outlined have been established for an initial period of several months, and the point score will be reduced when the number of surplus personnel returned from the European and the Mediterranean theaters makes this possible.

During recent weeks every effort has been made to speed the return of surplus personnel from the European and Mediterranean theaters so that a maximum number of Medical Department officers, especially Medical Corps officers, can be returned to the United States for reassignment and separation.

Although the original plans provided that the last of the surplus personnel would not be returned until the middle of 1946, it now appears probable that the entire surplus will be in this country shortly after the end of 1945. The major factors influencing the return of personnel from the Mediterranean and European theaters are the rate at which troops leave those theaters and the availability of shipping for the

return of Medical Department personnel. So long as large numbers of troops remain, a part of the surplus personnel must remain to furnish them medical care.

The rates at which Medical Corps and other Medical Department officers are separated are conditioned largely by the Pacific. If the Pacific did not exist, or if it could be ignored, as it clearly cannot, separations could be accelerated by approximately five months or more. When a surplus officer with a high score returns from Europe, he could be discharged. But if there are individuals with higher scores in the Pacific, a different procedure is indicated. The officer returning from the European theater, instead of being separated upon arrival, is granted a thirty day leave, plus an allowance for travel time from the port to home and from home to his new station. The individual who has not yet been overseas is granted a preembarkation leave of approximately fifteen days, which, when added to his travel time to the port and the period preparatory to sailing, amounts to approximately one month. Here we have two months. The trip overseas requires just under a month, or a total of three months. Travel time from the port to the new station in the Pacific, overlap on the job and travel time to the port of the officer returning to the United States eat up another month, or a total of four months. The trip home requires another month, or a total of five months. This is the minimum if the officer is separated on arrival. But if his points should be below those of an officer currently assigned in the United States, the process continues. The officer returning from the Pacific will receive a month's leave, additional travel time to and from his home, and only after he has been at his new station for approximately two weeks will the high score individual be released for separation. Here we had a total of seven months. Equity in separations means delay in separations of between five and seven months. Here is the explanation for the apparent paradox of how it happens that two months after V-E Day surplus medical personnel is just beginning to be released from the Army and why it will take many months before all of the surplus is finally separated. However, it is the Surgeon General's firm belief that the American public and the entire medical profession feel that the War Department's basic program of readjustment which includes the Pacific is sound and just.

Within the limitations of logistical requirements, especially transportation, the plan contemplates that the Army will point toward a reduction in the strength of the Medical Corps by approximately 7,000 by May of 1946. Because of the need to absorb the leave and travel time of replacements to the Pacific, not more than 4,000 of this number can be separated by the end of this year.

The transfer of several hundred thousand medical personnel in the midst of war, under great urgencies, involving three continents, represents the single largest undertaking of its kind in the history of the world and is dwarfed only by the still greater transfer involved in moving all Army personnel. To cope with this situation of unparalleled magnitude, the Surgeon General has evolved, after the most careful consideration, a detailed plan which he believes will secure the end desired by all—the finest medical service for the American soldier and the highest degree of equity for the officers and men of the Medical Department who are provided this service.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Manuel E. Lichtenstein

Lieut. Col. Manuel E. Lichtenstein, formerly of Chicago, was recently awarded the Brazilian decoration "Medal de Guerra." The presentation was made by General Mascarenhas on May 29, 1945 in the name of the President of Brazil. Dr. Lichtenstein organized the medical staff of the Brazilian expeditionary force assigned to an evacuation hospital and successfully established the practice of modern surgical methods for the care of battle casualties among Brazilian troops during the Italian campaign. Dr. Lichtenstein is also the recipient of the Bronze Star (THE JOURNAL, April 21, 1945, p. 1059). He graduated from Rush Medical College, Chicago, in 1925 and entered the service Oct. 15, 1942.

Major Brendan P. Phibbs

For meritorious service in supervising and aiding in the organization for the evacuation of the wounded, Major Brendan P. Phibbs, formerly of Winnetka, Ill., was recently awarded the Bronze Star. As a surgeon with the headquarters of the combat command battalion of the 12th Armored Division, Major Phibbs frequently exposed himself to enemy fire to see that evacuation was accomplished expeditiously and by the safest routes. Dr. Phibbs graduated from Northwestern University Medical School, Chicago, in 1942 and entered the service in June 1942.

Captain Sherwood P. Burr Jr.

Capt. Sherwood P. Burr Jr., formerly of Eugene, Ore., was recently commended by Major Gen. Robert Douglass, commanding the 7th A. A. F., for his work with the 11th bombardment group, which participated in almost every major move of the offensive that has rolled the Japanese back more than 3,000 miles. Dr. Burr graduated from the University of Oregon Medical School, Portland, in 1939 and entered the service Sept. 5, 1941.

Major Leonard S. Shemanski

Major Leonard S. Shemanski, formerly of Menasha, Wis., was recently awarded the Bronze Star for "meritorious achievement in connection with military operations against the enemy in Luzon, Panay and Negros, Philippine Islands, from Jan. 9, 1945 to May 1, 1945." Dr. Shemanski graduated from Marquette University School of Medicine, Milwaukee, in 1934 and entered the service July 15, 1941.

Captain George C. Blanchard Jr.

Capt. George C. Blanchard Jr., formerly of Augusta, Ga., was recently awarded the Bronze Star. The citation accompanying the award reads, in part, "Captain Blanchard, a battalion surgeon, was faced with the problem of setting up an advanced aid station in Strass, Germany, to take care of a large number of wounded infantrymen while the town and approaches to this town were yet under heavy shell fire. Vehicles which had attempted to get into the town, including tanks, had been knocked out and evacuation was impossible, initially. To minimize suffering and to prevent all possible loss of lives, Captain Blanchard made his way into the town before all the enemy resistance had been reduced. He was unable to find time to rest for many hours. His action saved the lives of many and his action is a credit to the medical profession and to the service." Dr. Blanchard graduated from Cornell University Medical College, New York, in 1942 and entered the service July 3, 1943.

Captain John B. Condon

Capt. John B. Condon, formerly of Chicago, was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy from Feb. 4, 1945 to Feb. 12, 1945 in France, while located at Fortschwihr, when the clearing station under Captain Condon's command was forced to operate considerably under strength. Casualties required the constant care of this medical officer, and exceedingly adverse weather conditions added considerably to Captain Condon's problems, as he was forced to operate in tents. The superior performance of duty rendered by this officer reflects great credit on himself and on the Medical Corps." Dr. Condon graduated from Loyola University School of Medicine, Chicago, in 1940 and entered the service Jan. 5, 1943.

Captain George A. French

The Silver Star was recently awarded to Capt. George A. French, formerly of Appleton, Wis., for gallantry in the European theater, April 4, "when he advanced across a bridge under direct enemy observation and a rain of fire to care for the wounded until evacuation was possible." Dr. French graduated from Marquette University School of Medicine, Milwaukee, in 1942 and entered the service Aug. 11, 1943.

VETERANS

OUTPATIENT TREATMENT FOR VETERANS

Thirty-one mental hygiene clinics and intensive treatment courses in nineteen neurosis centers connected with general medical and surgical hospitals have been authorized by Brig. Gen. Frank T. Hines, Administrator of Veterans Affairs, for the outpatient treatment of veterans with service connected disabilities. The clinics will make treatment readily available to veterans disabled in service who are in need of reorientation and will aid the veteran in returning to normal life and a gainful occupation in the shortest time possible. The outpatient clinics will be located at the following hospitals or regional offices: Boston; Hartford, Conn.; New Orleans; Cleveland; New York; Pittsburgh; Providence, R. I.; St. Louis; Washington, D. C.; Louisville, Ky.; Minneapolis; San Francisco; Atlanta, Ga.; Cincinnati; Dearborn, Mich.; Indianapolis; Newark, N. J.; Milwaukee; Denver; Jackson, Miss.; Seattle; Huntington, W. Va.; Bay Pines, Fla.; Columbia, S. C.; Des Moines, Iowa; Omaha; Memphis, Tenn., and Batavia, N. Y., though this clinic may be in either Syracuse or Buffalo.

Neurosis centers will be located at Aspinwall (Pittsburgh); Atlanta, Ga.; Batavia, N. Y.; Bay Pines, Fla.; Brecksville (Cleveland); Bronx (New York); Des Moines; Fort Howard, Md.; Hines (Chicago); Huntington, W. Va.; Indianapolis; Jefferson Barracks (St. Louis); Kecoughtan, Va.; Portland, Ore.; Minneapolis; San Francisco; West Roxbury (Boston), and Wood (Milwaukee).

Each outpatient clinic will be fully equipped for diagnosis and treatment, with facilities on hand for x-ray and clinical laboratory examination. The neurosis centers will be equipped for intensive therapy of the severely affected neuropsychiatric patient and will have available equipment for therapy embracing psychotherapy both for the individual and for the group; narcoanalysis and hypnotism for the purpose of exploring the subconscious in the same manner used in Army and Army Air Forces hospitals abroad for the treatment of the severely affected psychoneurotic.

In both types of clinic occupational therapy, psychotherapy, recreational therapy and social services, all aimed at an early reestablishment of the veteran in his home community, will be provided.

The clinics and neurosis centers will be placed in operation just as rapidly as qualified personnel can be obtained. Some psychiatrists and other personnel have been attending courses in the Army's Mason General Hospital, Long Island, N. Y., and other personnel is being sought by the Veterans Administration through recruitment.

ARMY

A VOICE FOR THE BATTALION SURGEON

To the Editor:—I would appreciate the following being printed. With the consideration to Major Gen. P. R. Hawley's open letter "Correspondence Concerning the Medical Department," in the Medical Bulletin ETO Number 30, April 1945, I feel that I can speak for my colleagues, the battalion surgeons, many of whom have endured the yoke far longer and with better grace and equanimity than I.

The Medical Department has done a wonderful job during the emergency. Those of us who came in as reserve officers early in 1942 realized the urgency of our then precarious military position and cooperated fully. Troop units had to be manned with competent agreeable and vigorous doctors. There is admittedly nothing professional about the work of a doctor with troops. The work is further complicated by manifest and deliberate attempts on the part of some low moral calibered soldiers to shirk their attendant responsibilities in the line. Moreover, the lack of apparatus for diagnosis, the uncertainty of supply, the desire of some commanders to delimit the size of sick call by devious means, including coercion and the threat of extra duty, plus the pitiful dependence of the first echelon surgeon on rear echelons who are inclined to look down their noses on this poor relation colleague who so rarely can make the correct anatomic and pathologic diagnosis, being without the instruments, x-rays or laboratory facilities for such, makes the first echelon medical officer bitter in time, especially since, having done so much with so little for so long, he becomes indispensable in this assignment and is never made available when and if in his meager opportunity to associate in professional channels he does meet a former teacher colleague or class mate who is in a position to offer a more fertile field for professional endeavor.

The ultimate control of the military destiny of a medical officer by a field officer is unjust. The practice of keeping medical officers either in hospitals or in field units is unjust, more especially when the time period concerned runs into its fourth year. I realize that any medical officer can do well in a hospital. I also realize that many medical officers cannot do well in the field, either through defects in health or by deliberate misapplication. I realize too that the talents of many true specialists would be wasted in such field units and I do not contemplate such waste. I speak only for that horde of little men whose professional, political and military friends are not highly placed; those young men with excellent education, training and military records of efficiency behind them who, because of a T. O., can never rise higher in rank, who because of being members of A. G. F. are not eligible for transfer to hospital units of the A. S. F. I speak of men who can only lose professional skill by this enforced, and now after three full years, unwilling further retention in that type of medical service which many younger men could carry out to much better military advantage. I speak of those men who, when they return to civilian practice, will return at a great professional disadvantage from pure lack of association, lack of opportunity for doing and seeing and reading, engendered almost entirely by a short sighted policy of assignment, reassignment and rotation, which no belated special superficial and impersonal refresher course will ever to able to overcome.

WALTER E. VOGT JR., CAPTAIN, M. C., A. U. S.

NOTE.—The communication of Capt. Walter E. Vogt Jr. has been discussed with various leaders in the field of military medical services. The consensus seems to be that the ordinary young doctor without special training can be rotated. The young man who has had two or three years of residency in a specialty is more valuable to the patient than one without such training and is therefore more valuable to the Army Medical Department for services in its specialized hospitals. Since hospitals are, for the most part, staffed with trained men, only general practitioners are left for purposes of rotation. Years of experience have shown that it is impossible to place any physician in a front line unit without training in a number of subjects which are never taught in medical schools. These have to do with the subjects of self protection under fire, cooperation with troops and similar matters. Medical officers in general cannot agree with the statement of Captain Vogt that "there is admittedly nothing professional about the work of a doctor with troops." If this was true the Army could easily put lawyers and railway engineers in positions now occupied by many physicians. Even men especially trained under medical leadership as first aid assistants find certain medical conditions which require the personal attention of a physician.—ED.

NEW CHIEF AT VALLEY FORGE

Lieut. Col. Steige D. Blackford, Charlottesville, Va., was recently appointed chief of the medical service at Valley Forge General Hospital, Phoenixville, Pa. He succeeds Lieut. Col. Maurice A. Schitker, Toledo, Ohio, who has left for an overseas assignment.

Colonel Blackford recently returned to this country after thirty months' service as chief of the medical service of the 8th Evacuation Hospital in North Africa and Italy. He was awarded the Legion of Merit for his work with that hospital.
